THE

JOURNAL OF HORTICULTURE

COTTAGE GARDENER,

AND

HOME FARMER.

A CHRONICLE OF COUNTRY PURSUITS AND COUNTRY LIFE, INCLUDING BEE-KEEPING.

EDITED BY JOHN WRIGHT, F.R.H.S., V.M.H.

Established

in 1848.

VOLUME XXXVI. THIRD SERIES.

JANUARY—JUNE, 1898.

LONDON:

PUBLISHED FOR THE PROPRIETOR, 12, MITRE COURT CHAMBERS, FLEET STREET, LONDON, E.C.

LONDON:
PRINTED AT THE "JOURNAL OF HORTICULTURE" OFFICE,
12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

TO OUR READERS.

"Be silent, 'tis an unerring way
When you nothing have to say."

Several years ago the founder of the *Journal of Horticulture* introduced the above couplet as a heading to one of his half-yearly prefaces to the index of a completed volume, then one of many which had gone before.

He had nothing to say beyond a brief, yet sincere expression of appreciation of the efforts of all who had aided him in its production—nothing but satisfaction with the position that "our Journal" had attained as the favourite weekly of so many lovers of gardening in many lands—nothing but confidence in the future so long as some of the best gardeners and accomplished writers rendered its pages agreeable, interesting, and useful.

As it was in the past so it is to-day—the same sincere appreciation of the aid of co-workers, the same satisfaction to those who are responsible for the production of the old favourite, and the same confidence in the future. The policy of the past will be preserved, and no change made except towards improvement, and this in the form, not of forcing methods, but of healthy natural growth, like that of a thrifty tree deeply rooted in generous soil.

And this reference suggests one word more. Before the next half-yearly volume is completed the *Journal of Horticulture* will have entered on its Jubilee year. That it has been useful to thousands in the past is a fact we would fain hope none will dispute, and we know a host of friends will wish for it a long career of future usefulness.

INDEX.

- Achimenes in baskets, 426
 Adiantum cuneatum roots infested with Vine weevil, 46
 Adonis vernalis, 462
 A "Dull Journal" and lively discovery—a lesson from life, 6
 Aerides Fieldingi, 533
 Agapanthus umbellatus for permanent beds, 132
 Akebia quinata, 261
 Allamandas and their culture, 319, 348; A. Williamsi, 348
 Allotments and cottage gardens in Surrey, 11
 Alpine flowers, brief notes on, 18, 87, 192, 262, 328, 393; sowing seeds of, 150
 Altrincham, a day at, 65
 Alyssum montanum, 328
 Amaryllis, the, 300; at Chelsea, 330
 Ammonium, silico-fluoride of, 521
 Ampelopsis Veitchii, 109
 Andromedas, poisonous, 580
 Anemones, planting, 22; and R. nuncius, 326; from seeds, 327; St. Brigid, 413
 Angraecum sesquipedale, 77
 Anguloas, notes on, 390
 Annuals, and biennials, the Sherwood cnp for, 142; for cuttings, 246; half-hardy, 267
 Antirrhinums, 67
 Apples—Stirling Castle, 35; Adams' Pearmain, 66; Court Pendu Plat, 81; Lord Hindlip, 155; stocks for, 205, 239; old trees, 228; Bramley's Seedling, 235; Lane's Prince Albert, 278; disbudbing, 356; Calville Rouge, 425; Golden Pippin as a decorative tree, 498; twigs blighted, 544; leaves diseased, 544; trees diseased, 545
 Apricots, culture of, 31, 89, 121; stocks for, 193; protecting, 226; disbudbing, 356
 April, flowers, 342; characteristics, 366
 Aralias, grafting, 71
 Arenaria balearica, 262
 Arisemas, 197; A. Wrayi, 197
 Artichokes, white Jerusalem, mould on, 114; Globe, 341
 Articles, labour saving, 538
 Arum Lilies, 483
 Asclepias tuberosa, 525
 As of a dream, 9, 98, 244
 Asparagus, planting, 314; notes on, 350, 527
 Asphalt path, making with cold tar, 381; making, 416
 Asters, notes on, 267; for exhibition, 473
 Aubrietia tauricola, 323
 Aucubas, variegated, propagating, 70
 Auriculas, a note on, 144; Southern show, 377, 395; transplanting, 452; ancient and modern, 516
 Australian forestry, 67
 Azaleas, Indian, notes on, 232, 278; in useful company, 374; hardy, propagating, 472
 Barr, Mr. Peter, and his travels, 302
 Beans, Runner and Broad, 80; dwarf, Syon House, 407; Wythes' Improved Mohawk, 428; dwarf and runner Kidney, 487; topping and thinning, 527; pests infesting, 545
 Bedding designs, 369
 Bedding, ideas for, 322
 Bees—Progress of bee-keeping, 21; sample of honey obtained, 21; finding a market, 21; making candy, 45; how to feed bees with candy, 45; the weather, 69; breeding in winter, 69; enemies, 69; a promise fulfilled, 70; British *versus* foreign honey, 92; have prices advanced? 92; sending comb honey by post, 92; large hives, 113; large yield of honey, 113; standard frames, 113; large *versus* small hives, 135; the doubling system, 135; using queen excluder zinc, 135; large frames, 136; how to procure a surplus, 153; shallow frames for supers, 153; full sized frames for supers, 158; a wonderful colony, 158; how to test the laying powers of queens, 158; a supposed mistake, 158; straw skeps, 179; obtaining a surplus from skeps, 179; supers on skeps, 179; size of hives, 179; how many eggs will a queen lay? 180; doubling, 180; notes on bee management, 199; fertile queens, 200; weight of honey obtained, 200; hives and frames, 200; the weather, 227; examining stocks, 227; feeding, 228; doubling hives, 249; the queen's laying powers, 249; using old combs, 249; how to make a large hive, 249; frames, 249; supers, 250; current work, 270; examining old combs, 270; reducing entrances, 270; condition of stocks, 291; dearth of dead bees, 291; queenlessness, 291; seasonable notes, 313; whence pollen is obtained, 313; pollen-producing flowers, 313; removing spare combs, 336; uniting weak colonies, 336; robbing, 336; spring management, 357; feeding, 357; perforated zinc floors, 358; dysentery, 380; starting bee-keeping, 398; bees in skeps, 398; the weather, 416; flowers on which bees work, 416; management of stocks and swarms, 416; foul brood, 494; hives for general use, 494; size of frames, 452; frames parallel to entrance, 452; timely attention, 471; swarms—dead drones, 471; preparing for a surplus, 489; enlarging the brood nest, 489; obtaining honey, 509; honey production, preventing swarming, 527; stray swarms, 543; artificial swarms, 543
 Beet, 321
 Begonias—Hybrid winter flowering, 12; B. Ensign, 12; B. Winter Cheer, 13; tuberos, from seeds, 45; Gloire de Lorraine, 201; raising tuberous-rooted, 298; Commodore Dewey, 506; Mrs. F. Sander, 506
 Belgium, a Briton in, 386, 459, 516; enriching manure, 516; Van Geert's nurseries, 517
 Birds and fruit buds, 358
 Blackthorn winter, 378
 Blood manure, 229
 Bocconia cordata, 32
 Boiler leakage, 292
 Books for R.H.S. examinations, 93
 Borecole, culture of, 319
 Boronia, megastigma, 293; heterophylla, 374
 Bouvardias, culture of, 450
 Boxes, coating with creosote and tar, 359
 Box, planting, 70
 Broccoli, and Cauliflower, 141; varieties for succession, 259; at the Temple, 462; diseased, 534
 Brownias, 184
 Brussels Sprouts, 258
 Buckwheat, sowing, 271
 Bulbs, increasing, 472; review of hardy, 523
 Bullfinches *versus* chaffinches as bud destroyers, 299
 Cabbages, growing, 82; early, 164, 387, 424; seven feet high, 349; the Beaconsfield, 505
 Caladium Lord Annesley, 506
 Calathes, notes on, 29
 Calceolarias, for bedding, 278; abnormal, 314; herbaceous, 331
 Californian experiments, 66
 Callas, leaves spotted, 314
 Calochortus Purdyi, 506
 Camarotis purpurea, 533
 Camellias, notes on, 100, 191; reticulata, 260; in the open air at Windsor, 467
 Camphor in Australia, 34
 Canker in fruit trees, 314; and pruning, 323
 Canna disease, the, 34; Mosaic, 506; Mrs. W. Marshall, 506
 Caper plant, the, 337
 Cardoons, 60

BARR'S SEED GUIDE for 1898
IS NOW READY,
And will be Forwarded Free on Application.

Barr's Seed Guide for 1898 contains a select List of the best Vegetable Seeds and most beautiful Flower Seeds. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. Sent free on application.

Barr's 21/- Collection of the Best Vegetable Seeds contains 14 Pints of Peas (best successional sorts), 6 Pints of Beans (Broad, French, and Runners), and a liberal Assortment of other Vegetable Seeds, for One Year's supply. For full particulars see Barr's Seed Guide, free on application.

Barr's 10/6 Collection of Choice Flower Seeds contains a liberal selection of the most beautiful Annuals and Perennials. Full particulars in Barr's Seed Guide, in which will also be found many sterling Novelties for 1898.

All Seeds sent Carriage Paid on receipt of remittance.

BARR & SONS,
12 & 13 KING ST., COVENT GARDEN, LONDON

SPRING CATALOGUE

For 1898,

Vegetable & Flower Seeds

AND

BULBS & PLANTS
IS NOW READY.

Will be sent Post Free on application to their Offices at OVERVEEN, near HAARLEM, HOLLAND, or to their GENERAL AGENTS—

Messrs. MERTENS & CO.,
3, CROSS LANE, LONDON, E.C.

No. 915.—VOL. XXXVI., THIRD SERIES.

SUTTON'S

AMATEUR'S GUIDE IN HORTICULTURE FOR 1898

Contains full particulars of

The Best Vegetables for the Table;
The Best Disease-Resisting Potatoes;
AND
The Most Beautiful Flowers.

The Most Complete Seed Catalogue issued. Profusely Illustrated with 194 Illustrations.

PRICE 1/-, POST FREE.

SUTTON'S ABRIDGED LIST OF VEGETABLE AND FLOWER SEEDS.

Especially suitable for owners of Small Gardens.

It is beautifully illustrated and contains descriptions of the BEST VEGETABLES, POTATOES, and FLOWERS.

Gratis and Post Free on Application.

SUTTON'S SEEDS
GENUINE ONLY FROM SUTTON & SONS, READING.

CHRYSANTHEMUMS!

All the New and Choicest Varieties.

CALVAT'S NOVELTIES FOR 1897,
YELLOW MADAME CARNOT, &c.
Strong Plants and Cuttings at moderate prices. FULL CATALOGUE POST FREE.

Journal of Horticulture.

THURSDAY, JANUARY 6, 1898.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

NEW YEAR'S ADDRESS.

I FEEL it to be a special privilege, as indicated last week, to be permitted again to send my annual greeting to the readers of "Our Journal." While our minds have during the past year been, so to speak, saturated with jubilees, the present year indicates another which ought to be peculiarly grateful to its readers, for it was in 1848 that the *Cottage Gardener* first made its humble appearance in the city of Winchester, whence it emerged to take its position as a well recognised organ of horticulture under the name which it has since retained, the *Journal of Horticulture and Cottage Gardener*; and yet, like all things here, this pleasure is mixed with sorrow, for one cannot but think how rejoiced Dr. Robert Hogg (who had for so many years as first joint editor, and afterwards sole proprietor, guided its destinies) would have welcomed the completion of its fiftieth year of true service to the cause he had so much at heart.

When on the threshold of a new year one naturally takes a glance over the past, and the working of the different agencies as influencing the future of gardening. Last week I could only refer to a special and historical act of the Royal Horticultural Society; but its ordinary work demands attention. This has been carried out in the same effective way which has characterised it during the last few years. There may be some combative people who regret the stormy days of South Kensington, but I think they must be very rare, and that all must rejoice in the more peaceful and prosperous time on which the Society has fallen. It is now in very deed what its name imports; its officers are men who are deeply interested in the pursuit which this is designed to encourage, and harmony and good feeling pervade its meetings. Its two great exhibitions, the one at the Temple in May, and the great fruit show held in the Crystal Palace in the autumn, have both maintained their high character; in the former everything that is noticeable in floriculture, from the stately Orchid to the humble hardy plant, is to be seen, while the grand display of the British-grown fruit at the show at the Crystal Palace has tended much to the encouragement of fruit growing in our own

islands, and the lessons taught by it ought to prevent the great mistakes that have been made in times past. Strong things have been said upon the subject of waste in our orchards, but not any stronger than it deserves.

The fortnightly meetings at the Drill Hall have brought together not only splendid collections of plants, flowers, and fruit, but also every novelty that is worth recording. The awards of the Committees are eagerly looked for, and the "imprimatur" of the Society is always regarded as an important commendation of the subject brought forward. Of course mistakes are sometimes made, but no one can have noticed the careful consideration which is given by the Committees to everything brought before them but must recognise the value of their awards. It is still a matter for regret that no more suitable place has been found for these exhibitions, and also that the attendance of visitors is so small. I think, perhaps, that this has been a little better during the past year; still, when one sees the room filled with the most admirable productions, and recognises how almost universal is the love of flowers amongst us, it does seem strange that so few even of the Fellows of the Society who live in London come to these exhibitions.

The Society has also carried out its plan of bringing its influence to bear on horticulture in the provinces; its failure in times past to run an exhibition of its own in our provincial towns made the Council very chary of attempting anything of the kind again, and a plan which they have adopted of some members of the Council visiting one or more of the provincial exhibitions of other societies in recognition of provincial work and awarding medals, has no doubt stimulated horticulture in the places visited, and at the same time formed a link with the great centre in London.

With regard to other horticultural exhibitions I hardly think the Royal Botanic Society has made much progress, although a certain amount of energy has been put into it, and the authorities have expressed a wish for other societies to hold their exhibitions there. The Royal Aquarium, which everyone abuses, and deservedly so, as the most hateful of all places for a flower show, may be regarded as the head quarters of the National Chrysanthemum Society, whose grand exhibitions are held there, though many supporters of the Society do not visit them, or do so in a very hesitating manner. The Crystal Palace, on the other hand, which is the best of all places for a flower show, has by the loss of its late garden superintendent, Mr. Heat, made it the more trying for his successor, Mr. Caselton, in that he had to come into office in so upsetting a year as that of the Jubilee, and both the National Rose Society and the Royal Horticultural Society have been very much interfered with by the arrangements made for its celebration.

A preposterous idea has been lately put forward in some quarters that the Government should buy the Palace for the use of the nation. I call it preposterous, because it could never be of any use to the London public, being too far out, and because the continued maintenance of such an institution would be such that no Chancellor of the Exchequer would care to be responsible for, and produce his balances on the subject. It might suit some shareholders to get something for their investments, which I am afraid they do not now, but it is to be hoped that the day may be far distant when such a project may be accomplished.

Horticultural societies throughout the kingdom have been carried on with their usual varying results, very much depending on the state of the weather on the exhibition days, for a wet day seriously cripples any society. The York Gala Fête met with a terrible catastrophe. It was held during the midst of that tremendous storm in June; the tents came down upon the plants, and I am told by those who witnessed it that a more pitiable sight could not be imagined. The Royal Botanical Society of Manchester has also been in a transition state. The death of its able and indefatigable Superintendent, Mr. Bruce Findlay, was indeed an irreparable loss, but there is so much energy in horticultural matters in Manchester, that I have every hope that the old Society will renew its youth. I think that horticultural exhibitions are more in favour in the West of

England than they are in the East. I can recall nothing eastwards that will at all correspond with the fine shows held in August at Taunton, Weston-super-Mare, Yeovil, and other places. A good deal of this is owing to the fact that the gentry of the neighbourhood make it a point of regarding it as a day with which nothing else is to interfere, but I think it is more than ever evident that flowers in themselves will not attract the multitude, and something has to be added. For instance, at Taunton the exhibition would be an absolute failure financially were it not for the fireworks in the evening; while at York and Shrewsbury the exhibition is more like a great fair than a show of flowers. It is a pity that such societies should be able to quote the Royal Botanic Society as an example they are to follow.

With regard to the taste for flowers I observe no diminution, although I think we may see that it runs more for decoration year by year. One cannot fail to notice how completely in the Carnation and Picotee the old florist varieties have been put into the background by the new Fancy and border varieties, just as already the Fancy Pansy has ousted the old florist kinds; and now the Cactus Dahlia seems to be coming completely to the front, while the old florist varieties, which do not lend themselves to decorative purposes, are, comparatively speaking, neglected; just as in the Chrysanthemum, the Japanese varieties are so much more in favour than the incurved, although I think the mammoth Chrysanthemums are of little use for decorative purposes. I see signs of a revolt against these enormous flowers, whose size appears to be gained at the expense of colour. We get a very large number of new flowers—yellow, white, blush, and light shades of pink; but flowers of such brilliant colour as Cullingfordi, Jean Délaux, and Julia Lagravère we look for in vain. Of what use is it to have these mops of wishy-washy colours? but if you go to a nurseryman and ask for some of those older flowers the chances are ten to one whether you can find them, and as long as such a number of certificates and awards of merit are given to the pale-faces I do not think the evil will become less.

The special societies which encourage the more popular flowers have had a varied experience during the past year. There are some persons who decry these societies; they think that everything ought to be connected with the Royal Horticultural, and that their exhibitions ought to be held under its auspices. I daresay, as a matter of theory, most growers of flowers would wish for this, but there are various objections to such a course. There is no place in which the Royal could offer to hold such exhibitions as those of the Rose and the National Chrysanthemum Society, nor is it in such a condition financially as to offer the substantial subsidies which other public bodies are enabled to do. There are five of these special societies—the Auricula, Chrysanthemum, the Carnation and Picotee, Dahlia and Rose. Of these, the first is the only one that holds its shows at the Drill Hall, the exhibits occupy little space, and though complaints are made of the bad light, yet, after all, it is convenient, and its meetings are generally a success; so it has been this year, and I do not think there is any other meeting at the Drill Hall that is so well attended as that of this Society.

The Carnation and Picotee Society that has been so well fostered by Mr. Martin R. Smith, has shown a balance-sheet that other societies might well envy, but made a mistake this year, for which it has had to suffer. In an evil hour it linked its fortunes with those of the Royal Botanic Society, and as a result their fine balance has been greatly diminished. How could it be otherwise? The obsolete and antiquated methods of that Society are an effectual bar to any free movement. Some years ago the Society was anxious the National Rose Society should go there, and I was deputed to inquire into the matter. I did so, and came to the conclusion that it was utterly hopeless. The National Chrysanthemum Society has had a prosperous year; it is perhaps the most popular of our special societies, and fortunately the blooms resist a plague of smoke, which would be death to many other kinds.

The National Dahlia Society has had also a prosperous year, and closes with a good balance. Its exhibition was held in the Crystal Palace, the most noticeable feature of it being, as I have said, the

prominence given to the Cactus Dahlia. I hear, however, that the Committee has done a curious thing, offering a prize for twenty-four blooms, to be shown on a board, like the Show Dahlias. The entire merit of the Cactus section is that of suitability for decorative purposes, and how this can be gained by exhibiting in such a manner I cannot understand. The National Rose Society has now come of age, having been established in 1876. Many of its earlier friends have passed away, and perhaps more than any other Society of the kind it has been affected by what the witty Dean of Norwich called "Jubilitus;" but I have a firm belief that when we get over the "temporary chill" that it has sustained, it will still go on in its prosperous career.

I do not think that any great change has taken place during the past year in the taste for special flowers. Orchids still maintain their pre-eminence as the most aristocratic, highly valued plants for our glass structures, while for the humbler devotees of Flora we find the Carnation, Chrysanthemum, Dahlia, and Rose still maintain their position as the greatest favourites. It may be asked on what do I ground this assertion? Simply this, that they have secured a large number of "decorations," as the French call them, for new seedlings, and this is a very good test. A few years back the tuberous-rooted Begonia was very much in evidence, but very few varieties have received any award this year. In the same way some years ago single Dahlias were in high favour and received numerous awards, but now they are little thought of, other flowers having taken their place. In several instances, as in the case of the Begonia, the limit of improvement seems to have been reached, and such good flowers can be raised from mixed seed that the cultivation of named varieties has almost ceased.

There are three families of Orchids to which several additions have been made during the past year—Cattleyas, Lælias (under which we must include the new family of hybrids, Lælio-Cattleyas) and Cypripediums. Of Lælias there have been twelve; of Cattleyas twenty-one; and of Lælio-Cattleyas sixteen; a pretty good addition for one year, and I am afraid Orchid growers are running into the error for which they have been amongst the first to decry the florists—namely, for bringing forward a number of varieties which are not distinct from those already in cultivation.

Great complaints have been made with regard to the multiplication of awards to other flowers, and I think not without reason. Surely it is going "beyond the beyonds," as Paddy says, to give awards to sixty-six new Chrysanthemums and thirty-four new Dahlias! If these were all collected together and put before a grower he would be ready to tear his hair and use very strong language if he were told he had to grow all. There were only eight Carnations and ten Roses honoured, and therefore it is that in the two former flowers that the retrenchment, as far as rewards are concerned, should be used.

Our home raisers of Roses have, as usual, delighted growers with their productions. Messrs. Paul & Son of Cheshunt, Messrs. William Paul & Son of Waltham Cross, and Messrs. Alex. Dickson & Sons of Newtownards have all maintained the high position they have acquired as the raisers of new flowers; and whether it be amongst exhibition varieties or flowers suitable for the garden, they have made us practically independent of foreign raisers. Time was when we all eagerly scanned the French lists to see what was coming out; now we take the matter very calmly, and I believe very few amateurs ever see them. Over this change all true rosarians must rejoice. And now, my friends, farewell. All these subjects about which I have written suggest higher and nobler thoughts, for we are all led in that Book which God has given us to be a "lamp unto our feet and a light unto our paths," to look from things here to things above, and let us never forget that in the glowing descriptions to us of the future Kingdom the idea of a garden is not absent; and so may you, my brothers and sisters, while tending your plants and admiring their beauty, be led to look up from them to their Maker, and in them to realise all His wonder and power, who causeth the "bud and the tender herb to spring forth," and at last, when time is ended, may spend a glorious eternity in the Paradise of God.—D., Deal.

NATURE'S LAWS AS APPLIED TO TREES.

BRANCHES CONTROLLING CERTAIN ROOTS.

ALTHOUGH I have no scientific knowledge of the construction of a tree, I will endeavour to prove that certain branches almost solely control certain roots, more especially in trees or plants of quick growth.

In experimenting with trees that were not required, and intended to be cut down, it has been an easy matter for me to select a branch which would be, say, one-tenth or one-twentieth part of the entire tree, and by tracing the raised bark (which can generally be seen in quick-growing trees) to the base, it will be seen what roots the branch derives its principal supply from. If the root is severed the growth of that particular branch is checked; it has to depend upon support from other sources, and the branch is not likely to take such a prominent position in the tree again.

Should you sever or even bruise the bark on the root selected, and apply poison in the form of dissolved arsenic, if the tree is in full vigour it will be seen that in the next two or three days (according to the construction of the tree and climatic conditions), the branch will be perfectly dead, and in most cases it will not appear to injure the other branches. Should such trees as Poplars be operated upon it generally causes a strip of bark, extending from the branch to the root, to die, and yet in many other trees it does not appear to affect the outer layer; but although not visible to the eye it must interfere to some extent with future success. Such experiments should only be attempted where trees are considered to be of no value, and are intended to be destroyed.

I think the above will assist in proving that trees and shrubs which are depending upon several roots, and are making free growth, are built up in sections, each leading section controlling to a great extent corresponding leading roots, otherwise one branch could not possibly be killed by poisoning one root, but the whole of the tree would suffer accordingly.

Should a tree be planted within reasonable distance of water or soil that is more favourable for quick growth, the leading root is almost certain to be in that direction, and in such cases almost the whole of the tree can be killed by poisoning that root, if done at a time when it is depending upon it for its principal supply.

STAKING TREES.

This is work that is too often done when it would be better if the tree were left to Nature. I will try to explain the good and bad effects produced. By way of illustration we will suppose that tree No. 1 is planted. It may be an Oak, Elm, or Plane. It has been growing in nursery rows, is 10 feet high, 8 feet showing a clean stem. At 6 inches above the ground the stem is, say, 1½ inch in diameter, at 8 feet high three-quarters of an inch in diameter, and the roots are well regulated. We place a 4 by 4-inch stake or post, to stand 8 feet out of the ground; the tree is secured to the post at the top, and at three other places at equal distance; it is well supplied with water, but planted in rather an exposed situation. To make sure that the top of the stake or post will not move we place three or four strong wire supports at the top, and secure them by strong pegs in the ground.

At the end of three years under ordinary conditions the stem will be, say, 6 inches from the ground, 2 or 2¼ inches in diameter, and 8 feet from the ground 2¼ to 2½ inches in diameter. By close observation it will also be found that the roots near the base are very small for the size of the tree, and the largest roots are generally not so near the surface. Now, the cause of the diameter being reversed is controlled by the artificial support, consequently the tree has to provide for the greatest strain directly above the stake, which causes it to be larger and stronger than is required near the base.

We will plant another tree; this we will call No. 2. It is a similar tree to No. 1, and planted in the same soil and exposure, but supported only with three stays about 5 feet from the ground, each stay fastened to something that will allow the tree to move with the wind, say 12 or 15 inches in either direction. At the end of three years this tree 6 inches from the ground should be about 3 inches in diameter, and 8 feet from the ground say 1¾ inch in diameter. This tree has not had any unnecessary support, and is proportioned according to the strain placed upon it. The leverage has also been greater on the surface roots, and they are consequently the largest, and would continue to be the leading roots of the tree.

TAP ROOTS.

There is a diversity of opinion as regards tap roots. The largest trees that have come under my notice are almost devoid of a tap root, but are invariably composed of many leading roots of a uniform character, which are also capable of penetrating the subsoil to probably as great a depth as the same species that is trusting principally to a tap root.

Surface roots will in many instances send down tap roots. Perhaps the best specimen I ever saw in that way was last year on the river Murray at Denilquin in N.S. Wales. There was a Red Gum tree on the bank that could not be less than 30 tons in weight. The floods had evidently washed the soil away from the base of the tree, and roots had started under the leading surface roots some 8, 10, or 12 feet away. Each root had gone straight into the earth, and each one may now be called a tap root. There were seven or eight in number, and each one standing out of the ground 6 or 8 feet high, dividing the weight of the whole tree between them. This is another instance of the way Nature adapts herself to circumstances, and shows that wherever the strength is required endeavours to provide for it.

TREES IN OPEN SPACES.

Anyone who will take the trouble to go into the open fields or paddocks and examine large trees that are dotted here and there, they will find the most exposed trees have a tendency to form large spreading branches before the tree is any great height, and that the trunk near the base is of an irregular outline, many of the surface roots near the trunk being of an oval shape, caused by the excessive strain placed upon them in windy weather. In many cases they remain as stays or buttresses, and extend for some distance up the trunk; but where trees are growing closely together in the forests, and shelter each other, they have no occasion to provide for rough winds. The trunk is more of a uniform size, and the amount of roots in proportion to the top would probably not be half as much as would be required for an exposed tree.

ARTIFICIAL SUPPORTS FOR TREES.

No doubt there is something required in the way of supports for trees that are grown artificially that will reduce the excessive growth at the top, and increase the growth of the stems. It should be constructed in such a way that a tree may be secured from 1½ to 5 inches in diameter, and still allow the tree to move—say 6 inches each way—without chafing the bark. It would reduce endless tying, thinning, and pruning, but would require to be neat, cheap, and strong. — THOS. POCKETT, *Curator Public Gardens, Malvern, Australia.*

EARLY STRUGGLES FOR KNOWLEDGE.

(Continued from page 594, last vol.)

STILL keeping in view the object of mastering our own language, I bought Dr. Hugh Blair's "Lectures on Rhetoric and Belles Lettres," an admirable work of great interest, and this led to a long course of reading, in which the chief works were Addison's Spectator, Johnson's Rambler, Macaulay's Essays, Roscoe's Translation of Sismondi's Literature of South Europe, Goldsmith's, Pope's, Shakespeare's, Wordsworth's, and Longfellow's works, with a considerable share of fiction derived from the productions of Sir Walter Scott, Charles Dickens, Thackeray, Lord Lytton, and others.

History also furnished abundant reading, for besides acquiring a general idea of ancient history, especially as regards Greece and Rome, which I obtained from Keightley's books, and Plutarch's Lives, I bought at different times several works on British history. The Hon. Alex. F. Tytler's Elements of General History and a History of British Commerce were two books I found of much interest, but the greatest satisfaction was derived from the history of particular epochs, especially in connection with the Spanish Conquests in America. Prescott's Histories of the Conquests of Mexico and Peru I found most fascinating, and I have re-read them several times, for in their way they are unrivalled. The same author's Reign of Ferdinand and Isabella was a favourite, as were Guizot's General History of Civilisation in Europe, Alison's Philosophy and History of Civilisation, Humphrey's Manual of British India, and Burney's British Neptune (the history of the Royal Navy).

Of others, partaking of the nature of biography, Washington Irving's Life of Mahomet and the Successors of Mahomet, with Smollett's translation of Voltaire's History of Charles XII. of Sweden and Peter the Great of Russia, may be taken as examples of classical works that well repaid for close reading. No general biography influenced me like George L. Craik's Pursuit of Knowledge Under Difficulties, of which the two volumes contain abundant information of the kind calculated to encourage any youth who is anxious to improve himself. The books named are only those which had the greatest effect on my mind, they do not represent a tithe of what I actually read in the period, and the omnivorous character of my appetite may be judged from the range of subjects covered, extending from Fenelon's Adventures of Telemachus and Voltaire's Micromegas to Locke's Essay on the Human Understanding, Addison's Evidences of Christianity, Dr. Paley's Natural Theology, Pascal's Provincial Letters and the Letters of Junius. Some close study was given to logic as embodied in the works of Drs. Whateley and Watts,

and such methodical habits of thought, study, and work as I have formed have been due in a great measure to this portion of my reading.

Geography engaged much of my attention, and I had a great partiality for map drawing. In my book hunts I bought several Atlases of Ancient and Modern Geography, and I had one find which was invaluable to me—namely, A System of Universal Geography founded on the works of Malte-Brun and Balbi, which in a thousand pages of closely printed matter contained quite a cyclopædia of instruction, amply sufficient to satisfy my appetite for the time. Numerous volumes of travels were read, such as Captain Cook's Voyages, Washington Irving's Life of Columbus, and the Voyages of the Companions to Columbus, but two works stand out prominently amongst them all—namely, Charles Darwin's Naturalist's Voyage in the Beagle and Dr. Joseph Hooker's Himalayan Journals, which must be classed amongst the most interesting and instructive books of the kind in the English language. Besides these I spent many an agreeable hour over Hugh Low's Sarawak, Seaman's "Mission to Viti," Fortune's Residence Amongst the Chinese, Ellis's Visits to Madagascar, Frobel's Travels in South America, Bowring's Visit to the Philippine Islands, and Backhouse's Visit to Mauritius and South Africa.

It should be mentioned here that arithmetic was a favourite study, and was pursued concurrently with other subjects. I bought a manual issued to the schools in Ireland entitled The Theory and Practice of Arithmetic, which for simplicity and thoroughness I have never seen surpassed. Certainly it enabled me to wade through all the principal rules without any serious difficulties, and I passed from that to a study of book-keeping, of which a knowledge must be useful to every man at some period of his life.

Turning to science subjects, a long chapter could be written upon my struggles, but I must not tax the patience of the Editor and readers too severely. Apart from the numerous works read, for I bought all my narrow means would permit, and studied them diligently, I had the opportunity of attending many lectures by eminent authorities, including Professors Huxley, Tyndall, and Guthrie, with others, though this necessitated an eight-miles walk every time. I derived great benefit from this instruction. Notes were taken at each lecture, and written out fully afterwards, any difficulties being the subject for research, and this is one of the matters I have always followed out consistently; I could never rest satisfied until a difficulty was overcome, and no efforts were spared in this direction. Geology, physical geography, statics, dynamics, chemistry, and meteorology were in turn the subjects of my earnest attention.

Beyond this I was attracted by astronomy, and investigated this wonderful science as far as time and means would permit. For a few shillings I procured a second-hand pair of globes, terrestrial and celestial, and sufficient progress was made to work out most of the problems given in introductory text books, such as "Keith on the Globes." This, however, I was compelled to give up entirely, though most of the subjects named in this section, but especially chemistry and meteorology, occupied much attention later in my career, and still form favourite studies. In reference to the earlier books read on scientific subjects, I do not remember one that influenced me so much as Michael Faraday's Lectures on Physical Science, of which I was lucky enough to secure an edition prepared by Wm. Crookes.

My daily work in the course of the seven years named as the period of initiatory study covered the whole range of gardening—i.e., outdoor cultivation for vegetables, fruit trees, hardy plants, and ornamental trees, including the operations of digging, trenching, planting, pruning, grafting, budding, and seed-sowing. Under glass it included the cultivation of Vines, Cucumbers, Melons, Peaches, greenhouse plants (especially Heaths and hardwooded plants), stove plants, with Orchids and Ferns. Then, too, I had some special opportunities for learning which do not fall in the way of every youth; I had to assist in laying out some new gardens and in the erection of glass houses, the former giving an inclination in the direction of landscape gardening, and the latter led to the careful study of hot-water heating. In all this I had the advantage of a master's aid, one who loved his calling and who never tired of teaching and training those eager to learn. He gave me the benefit of his life's experience, and as he had commenced with a first-class education preparing him for a higher station in life he had, through a career of over thirty years, brought a trained intellect to bear upon his work which was evident in everything he undertook.—A WORKING STUDENT.

(To be continued.)

A PARK FOR VENTNOR.—The trustees of the estate of Mrs. Evans, the owner of Loftly Downrise, above Ventnor, one spot of which is the highest point of land in the Isle of Wight, have intimated that it is Mrs. Evans's intention to make the town a present of the Downs for the use and recreation of the public for ever. The Downs comprise several hundred acres, and the summit commands a wide range of view over the whole island and parts of Hampshire and Sussex.—("Times.")

EXOTIC NURSERIES, CHELTENHAM.

THE situation and condition of Mr. James Cypher's nursery may not be so well known as that of some of the great London establishments, but its reputation is unique. Thirty years ago Mr. Cypher began exhibiting plants, and he has done so annually ever since. During the last twenty years no show of any importance has been held in England at which he has not exhibited successfully. The largest plant classes are Mr. Cypher's forte, "twenty stove and greenhouse plants" being a favourite class, and in groups of any extent he is invincible; while in specimens or collections of Orchids he is equally successful. At such shows as Shrewsbury and York he frequently secures prize money amounting to upwards of £100, and collectively his winnings have amounted to many thousands of pounds. No exhibitor is feared, and although some growers may be jealous of the Cheltenham exhibits, they are always welcomed by show promoters, as they give the gatherings a tone and interest not obtainable from local exhibits.

A legacy on the demise of an employer, consisting of a small greenhouse and a few plants, formed the origin of one of the most successful plant growers and exhibitors of the nineteenth century. His first appearance in the show tent was with half a dozen Azaleas, for which he received the leading honour, and since then the prizes won are innumerable, and exhibits are frequently sent to two and sometimes three different shows on one day.

But to the nursery, which covers about 8 acres. This is situated in Queen's Road, Cheltenham, a most convenient position in a desirable town. Originally it consisted of the ground occupied by two glass houses. Now the extent named is Mr. Cypher's freehold, and more than half of it is covered with glass—a most creditable memorial to a self-made man. Being in Cheltenham now and again in times past, I have seen the nursery at various periods of the year, and it is at all times deeply interesting, as apart from the seasonable treatment being given to the show plants, there is a general nursery stock of small saleable plants in quite as good condition as the large ones.

THE ORCHID DEPARTMENT.

The Orchids comprise a most extensive and well-grown collection. There are three houses, 60 feet long by 18 feet wide, devoted to Cattleyas. Many of the plants are fine specimens in 10 and 12-inch pots, and others in smaller ones. All are remarkably well developed and luxuriant. The best varieties, such as Mossiæ, Mendeli, Dowiana, aurea, labiata, Trianae, Skinneri, Warneri, and Lawrenceana, are grown in quantity. The plants are arranged in the usual way on a gradually rising stage in the centre and on side shelves, and tanks of water are constructed underneath each of the stages. Dendrobiums find a most congenial home. Four houses are given up to them, and their growth and condition are remarkable. Here again only large numbers of select kinds are grown, the favourite varieties being nobile nobilius, thyrsiflorum, Dalhousieanum with pseudo-bulbs 6 feet in length, fimbriatum oculatum, Parishii, Wardianum, formosum giganteum, Phalænopsis Statteriana, P. Schröderiana, Ainsworthi, and many others. The pseudo-bulbs on some plants of nobile nobilius were over 3 feet in length and as thick as an ordinary walking-stick. One plant of this variety, propagated from a cutting eight years ago, and now a fine specimen, is composed of over 100 bulbs. These plants are grown in a suitable atmosphere when forming their growth, and were, when this visit was made, suspended close to the glass, where they will remain until they begin to flower.

Another most extensively grown section are the Cypripediums. Here I first saw that gem of the class insigne *Sanderæ* with its beautiful yellow bloom. Being late autumn and winter flowers the Cypripediums generally were in the height of their beauty. Like all the other Orchids the plants of various sizes were all in perfect health, and the collection is very complete in variety; but those which attracted my attention most were many especially fine forms of the old insigne, insigne Ernesti, giganteum Cypheri, with luxuriant foliage and a very large white dorsal, green base, brown slipper, and green, brown-lined petals, evidently a free-growing variety; Maulei, Chantini, Leeana superbum, Roezli, Lathamianum, nitens superbum, Morganæ, Schröderæ, Spicerianum in fine variety, T. B. Haywood, and Veitchi superbiens. In all there were thirty distinct Cypripediums in flower at the end of November, and their excellent growth and profusion of blooms indicated them as being especially adapted for amateur cultivation.

In the two Mexican houses there are numbers of specimens of *Cœlogyne cristata alba* and several others, all of which supply abundance of choice cut flowers in spring. *Odontoglossum grande* was fine, as were *Oncidium varicosum*, *Trichosma suavis*, and several of the *Lælias*. The Vanda house was extremely gay with profusely flowered specimens of *V. cœrulea* in different shades of pale blue, and some almost pure white. What a charming December Orchid this is! The cool Orchids were very striking in their great numbers and robust health. There are three houses given up to them. At the time of my visit there were eighteen *Odontoglossums* in flower, but the one most grown is *Alexandrae*, and a magnificent lot they are, some in flower and others producing spikes, and all in perfect condition. Other favourites are *Pescatorei*, *lutco-purpureum*, *Halli*, *gloriosum*, *Edouardi*, *Rossi*, and *Roezli*.

The *Aërides* have a small house to themselves. *Lycastes* are grown in quantity, while *Masdevallias* are very numerous, and so are the *Maxillarias*. *Phalænopsis*, so often seen in indifferent health, are absolutely at home. There were no fewer than 108 distinct Orchids altogether in flower on the 1st of December, and the condition of the

whole of the extensive collection reflects great credit on Mr. John Cypher, who takes this section of the nursery under his special care.

MISCELLANEOUS PLANTS.

The principal Palm house is 90 feet in length and 24 feet in breadth, and in it are located some of the grand specimens so much admired at shows. The *Kentias* are exceedingly fine, especially *Fosteriana*, *australis*, and *Belmoreana*. *Latania borbonica* was also fine, as were *Phoenix rupicola* and *Cocos Weddelliana*, all of which, besides being seen at shows, are made use of in connection with the many public decorations Mr. Cypher undertakes. The Arum house contained over 1000 plants all in flower or bud—an excellent arrangement, as there is an endless demand for them as Christmas flowers. These are planted out and lifted in September. Abundance of white *Lapageria* clothed the roof of this house. The Croton house is 45 feet in length and 24 feet in width. It is full to overflowing with large and small plants. Some of the show specimens which occupy the centre stage are 6 feet high, and as much through. They were all exceedingly clean, and I was informed that this was attributed to liberal syringing in the summer time, and the occasional use of Fir tree oil. Asked which were considered the best varieties, Mr. Cypher replied *Victoria*, *Baron James de Rothschild*, *angustifolium*,

FIG. 1.—MR. JAS. CYPHER.

(Photo by N. May & Co., Limited, Cheltenham.)

Chelsoni, *Mortefontaineensis*, *Thomsoni*, *Reidi*, and *Warreni*. As a house of beautiful foliage nothing could possibly excel what was witnessed.

The New Holland house was mainly given up to specimen plants of *Aphelaxis*, *Phœnocomas*, *Pimeleas*, *Staticeas*, and others; and the Heath house is also devoted to specimens of a size and in a condition rarely seen nowadays. Many of them are huge plants 6 feet high and as much in diameter, and in pots 18 inches wide. As a matter of fact, many of the plants are more amply provided with root room than is generally seen, and this, no doubt, helps to develop their splendid proportions. The *Allamanda* house is 30 feet long and 12 feet wide, and contains a variety of specimens which flower from May till October. There are many duplicates of all the show plants, without which it would be impossible to exhibit at a succession of shows during three or four months of the year. *Nobilis*, *Hendersoni*, and *grandiflora* are the favourite sorts grown.

Ixoras are largely grown, many fine specimens of *Williamsi*, *Fraseri*, *coccinea superba*, *Regina*, *Colci*, and *Duffi* being in evidence. *Bougainvilleas* also have a structure to themselves, and special attention is at present being paid to a new variety named *Cypheri*, which produces flowers hitherto unequalled in size and colour. *Staticeas* are abundant, as are *Anthuriums*, and many fine specimens of each were seen. There is a general Fern house 70 feet by 21 feet; but Ferns are not favourite exhibiting plants with Mr. Cypher. He prefers something more substantial. It is to the skill and attention of Mr. William Cypher that the fine growth and excellent condition of these large plants is mainly due.

So far as I could learn they are produced by ample root room, generous treatment during the growing season, and a thorough maturing of the growth after that is over, as this is said to give both foliage and flower of the highest quality. The specimen Azaleas are another feature

which should not be omitted. They are grown and trained in the old fashioned style, and such plants are rarely seen.

Apart from the successful attention Mr. Cypher gives to exhibiting, he also conducts an extensive nursery business, particularly in Orchids, indoor plants, and open air shrubs. The cut flower trade done, too, is most extensive, especially in bouquets, wreaths, and crosses, for which this nursery is noted. In years gone by many persons will remember Mr. Cypher as a most successful competitor in the dinner table and other decorative classes at shows. I have frequently admired the aptitude he displayed, and have told him frequently it was a pity he discontinued it. One of the most valued prizes Mr. Cypher has ever secured was when the Royal Horticultural Society held its show at Carlisle some fifteen or sixteen years ago, a show much noted for excessive moisture, if I recollect rightly. A local countess offered a twenty-five guinea cup for the best decorated dinner table, and Mr. Cypher won the coveted distinction; a mark, I think, amongst many others which stamps the recipient as a genius in all that relates to flowers. But I am deviating.

All kinds of decorative plants are quite as well grown as the large specimens. Three houses are given up to Maidenhair Ferns. Two large houses were full of December-flowering Chrysanthemums in fine leaf, and with a profusion of buds and bloom. The varieties grown for this time are Niveus, Lady Lawrence, Golden Wedding, and W. H. Lincoln. In the summer time these houses are devoted to Tomato culture. Many Bouvardias are grown for the usefulness and excellence of their flowers at this season. Carnations in pots also receive attention. Miss Jolliffe is a leading favourite, as is Lady Rothschild.

Greenhouse Rhododendrons are finely grown, and were bristling with flower buds like an Azalea. Fielder's White is regarded as the best amongst the latter for cutting. Its flowers are perfect, and it grows so freely that if 2 or 3 inches of wood and a quantity of foliage is cut off with each head of flower, the plant will, by another year, be as luxuriant as ever. Stephanotis are growing on the roof of several of the houses, the flowers being regarded as indispensable in summer for choice decorations. Lily of the Valley is also in great demand, and some 60,000 crowns are forced for the supply during the shorter days of the year. There are also houses devoted to Cinerarias, Primulas, Gardenias, Cyclamens, Camellias, Tea Roses, and other plants.

Upwards of seventy hands are employed in the nursery, and Mr. Cypher's style of dealing with these is original. He does not believe in his men as "rolling stock," consequently they are mainly permanent hands who have been taught in his own efficient way, and master and men live on terms of harmony to an extent that is not often experienced or seen.—PEREGRINE.

HERBS AND AROMATIC PLANTS.

(Concluded from page 604, last vol.)

ANGELICA and Anise are yet in some large establishments esteemed for confectionery purposes. The former, a biennial, if sown in early autumn will produce the following season sufficiently large leaf-stalks for candying, a purpose for which it is almost exclusively grown with us, although put to further uses on the Continent. Anise, an annual now seldom seen in cultivation, I found to be often in demand by an old-fashioned housekeeper, when our summers permitted the ripening of the seeds. Balm and Borage may be mentioned together, both being used in the concoction of claret cup, and woe betide the man who upon their demand is found wanting. However, a few roots of the first, a well-known perennial, will generally meet all requirements, and the annual Borage, when once introduced to the herb border, will eventually assert its right of being by running over the garden. Still to prevent errors, although few can mistake it either in or out of flower, it is best to keep a few plants to their own place; one man who catered for the kitchen having a predilection for gathering *Anchusa italica* in preference to the genuine article.

Fennel, one short row of which will be found sufficient, requires annually cutting down prior to seeding, thus keeping it to its own quarters. Like Borage it is of weedy habit, but indispensable to a collection. Chervil holds a prominent place among the herbs proper, and in some places is in daily demand. In this case several sowings from spring to autumn will be necessary, the latest producing strong plants to stand the winter without "bolting." The ubiquitous pot Marigold is seldom absent from old-fashioned gardens, with its cheerful blossoms, the virtues of which for culinary purposes are now rarely recognised. The improved forms are, indeed, worthy of space in any mixed borders or otherwise, but I still have a *penchant* for a single line on the herb border of the old deep-coloured single variety, which charmed me as a child in the long ago.

Burnet, Caraway, Clary, Coriander, Costmary, and Dill one need hardly descant upon. They are old-fashioned, practically "out of date," hence the reason room was found for them on my herb border. Tansy, too, enters into modern cookery, although its elegantly curled foliage is distinctly ornamental; however, once introduced it is a thorough vagabond, insinuating itself amongst the most substantial of Box edgings. Still, with all its faults I can tolerate it, and for rough decorative purposes, where its highly aromatic perfume is not its ban, I have found it useful for cutting. Chives are often called for by a

French *chef*, and Garlic, to which a small bed may be devoted, with the same treatment as for Shallots, which are equally important, will suit, unless grown on a larger scale. A good manuring, with a well firmed soil, and early planting, will give good ripened bulbs for harvesting ere summer is out.

Rampion, a biennial, the nutty flavoured roots of which are occasionally used in salads, was in one place, where salad making was studied as a fine art, considered to be indispensable. Sorrel, under one or other of its forms, is often called for, but seldom, perhaps, in sufficient quantity to require more than two or three lines of it finding a place on the herb border. The common Sorrel is well known, but there is a round, glaucous-leaved variety, of much more pronounced acidity now rarely met with, but well worth having. Horehound, Wormwood, and Rue, all easily raised from seeds, will invariably be found in a good collection. The merits of Chamomile are, I think, sufficient to justify one, at least, of our beds, as previously outlined, being planted with it; the annual crop of blossoms may be gathered at intervals, as they develop, for drying.

As the various kinds of herbs likely to be required for culinary purposes come to the blossoming stage, good bunches should be cut and dried. Some cooks prefer to do this themselves; but in any case it is as well to have an edition of this *hortus siccus* kept in the garden, each kind to be legibly labelled. Those aromatic plants which remain to be noticed, being chiefly of shrubby habit, may well claim a place in the background of our mixed borders. The principal of these are Lavender and Rosemary, each of which requires no pressing of their claims on those who love old-fashioned plants. A packet of seed of each will give vigorous plants for all purposes, any surplus lending additional interest and charm to the shrubberies or other part of the kept grounds according to circumstances. For the fragrant Southernwood one would fain ask a place, and *Aloysia citrodora*, the so called Sweet-scented Verbena, has charms so peculiarly its own, that no garden, great or small, should be without it; and where a little protection is necessary to insure its well being through the winter, none could grudge the labour thus involved. A small plant wintered under glass will, upon starting in the spring, provide slips easily rooted in a little heat.

Myrtles, two varieties of which, the broad and narrow-leaved, are commonly cultivated, are no less worthy of our regard, and a favoured spot under the shelter of a warm wall. The grace and beauty of the broad-leaved variety when studded with its simple flowers it would be superfluous to extol, whilst sprays of the narrow-leaved kind may well enter into the composition of any bouquet, however rare. Amongst things of lowly growth suitable for rockwork such deliciously perfumed and elegant little flowering plants as *Thymus minima* and *T. minima alba* must be named, and the pungent peppermint-scented *T. corsica*, probably the most odorous of the family, is a gem. Our list, although not exhausted, is, perhaps, for all practical or sentimental purposes, sufficiently comprehensive, hence one may conclude with the hope of eventually seeing a certain amount of interest revived in the matter.—HERBALIST.

A "DULL JOURNAL" AND LIVELY DISCOVERY.

A LESSON FROM LIFE.

"MR. EDWARD ESS, at the Hall, and I both think the last number or two of the *J. of H.* rather dull. He suggests that you might charter the Emperor for a lively series." That is what I have received on a postcard from the Editor, with the laconic request—"Find Ess, then trace 'I.' The postal stamp suggests they are in your district; find them and make the best of them."

I have long known how difficult it is for a gardener to make any kind of forecast of what he may be called on to do, and have been more than once astonished by the nature of things which were assumed to come within the scope of his "duty," and have tried to think of more in order that I might prepare myself to be up to anything; but in all my imaginings I never came within miles of anticipating being called on to play the part of detective or explorer, and that I should receive a missive to "find Ess," I think no one could anticipate such an outlandish surprise.

In ruminating over the matter, I was overcome by some peculiar influence savouring of the romantic, and another missive—an historical missive of the past—filled my mental vision. It, too, was from an Editor to a man of resource and great daring—"Find Livingstone." Oh, the vanity of poor humanity! What utter absurdity that I should, even in a momentary flash, feel myself a Stanley. We cannot, however, help the association of ideas. They just associate themselves in spite of us, and not many of even the most sober, sedate, and unemotional but who have not at some time or other played at "Kings and Queens." But, to come to facts, Livingstone was found, and so was "Ess and I."

I should like to see them now they have read so far of their discovery, and watch them change from hot to cold, and show it, wondering what is coming next. That postal stamp was fatal, and they will learn now of the stranger's call to "see the gardens" in the charge of one, and to gather "advice on Roses" from the other, for in this case was discovered a rosarian who swept the boards at local shows.

When fairly on the track of Ess, I naturally wondered what manner of man I should meet. Sprightly, lively, talkative, and briskly intellectual, I naturally pictured a personage who thought the "J. of H. a little dull." I found him the reverse—quiet, modest, a genuine gardener, and, without doubt, a plodding and evidently intelligent worker; but as to humour, not a trace was discoverable, and only the merest apology for a smile could be extracted from his placid countenance.

The fine old garden, intersected by broad walks, edged with *Sempervivum*, flanked by herbaceous borders, backed with espalier fruit trees, with vegetable quarters beyond, the whole enclosed in lofty walls covered with trees old and young; a long range of glass across the northern boundary, vineries, peacheries, plant houses; all and everything in order outside and in—such order that could only be maintained by an earnest man with the limited means at his disposal. All this was apparent; but it was not apparent why this comparatively silent man—a thinker evidently, a listener rather than a talker, and intensely practical—should think any garden literature dull; he rather suggested a shudder at a joke, and a squirm at light reading, as frivolous.

It was a puzzle. I had found my man right enough, but not solved the problem. On passing through the potting shed on the way to the fruit room the "Journal" came in view. "Hope at last," was my silent motto. I must fish warily. "Oh, I see you are a reader of this. How do you like it, and what do you think of it? It is practical, I fancy, but perhaps a trifle heavy at times." The last was rather a leading question, but as Mr. Ess did not write the card in my possession, and probably did not know of its existence, it was felt to be safe. "Yes," was his reply, "I have read it for many years, and have always liked it. As to what I think of it, I have often fancied it runs with the weather—sometimes bright, sometimes dull, and now and then gives us an article almost freezy; but I am not one who finds much fault with the weather, which I try to make the best of, and just now I want frost for filling the ice house."

A rather adroit "turn," I thought, for he did not say he had no fault to find with the Journal. I must try again; and thus proceeded, "That is very much my opinion, and I believe the weather affects writers; they seem to get dull as the leaves fall, and brighten up in spring and summer. I sometimes wish it was the other way about; and what we should do without the jolly Japs and the rest of them I really don't know." A hit, sir, a "palpable hit," for he brightened actually into a smile as he rejoined with promptitude, "That's exactly it; we do want something to 'liven us up. My Japs have not been bad, but we want something more. It is all very well for one writer to tell us in all seriousness how to dig, trench, and prune; another to forage among the funguses for all sorts of queer things with foreign names, and grope among worms, mites, and maggots as if he loved them. Then how one's jaded intellect is revived on being told that 'Brown was first with a fairly good stand, Jones second with one not quite so good, and Robinson third with another which might have been better' (?) Somebody likes all that sort of reading, no doubt, but I like something these long dull nights in this little dull place a bit more lively," and so on. I, however, interposed by asking what kind of matter he liked best. "Oh," he replied, "I am not particular so long as it is gardeny, and such as one can't help reading; but a good deal is so prosy that I am obliged to turn to the fiddle for relief."

How easy it is to be deceived in a man! This at first almost silent listener found his tongue when the right chord was struck; he also revealed his musical instincts; and he evidently appreciates the "music of words" or the sparkling of fancy—"gardeny" notes, set not in a minor key. Work not described, as if it made his back ache in reading it; nor science, dealt out in strings of dry didactics, to puzzle his brain (for he has one), and drive him to the dictionary or—the "fiddle."

Whether the wants of such men can ever be met is somewhat of a problem. It is something, however, to have discovered this particular man, and subjected him to a process of extraction; but the time for departure has come, his leader has to be found—the author of the card, the mysterious Mr. "I." He could not be very far away in such a small colony of rural settlers. To the casual remark, "Not

many gardens worth seeing in a place like this I suppose," the reply came, "No, there's only the Rectory, which is fair; the Grange, that is middling; and a smallish spot called the Fishponds, but I don't know why, for the only pond I have seen is a duck pond." Next thought, Do you know if any of them read the Journal? "No, I don't think the 'places' do" (oh!), "but I think it is read by the gardeners, and I know Mr. Walton takes it regularly, though he is a master." But who is Mr. Walton, I wonder? "Why, haven't you heard of Mr. Isaac Walton?" The subject was getting interesting. I had, of course, heard of "old Izaak," the angler. "Well," was the response, "I suppose our Isaac must be a descendant of his, but he is a better hand with the gun than the fishing rod, and he is strong on Roses." The very man. I want to know something about the new ones. "Then by all means go (tell him you have been here), and you will find a hearty welcome."

A ten-minutes walk brings into view a glimmering of water, and next a perfect snugger of a garden is entered; that is, a garden completely sequestered, with apparently something of many things in it, but most of all Roses, and evidently cherished. "Mr. Walton, I presume," and a slim dark gentleman, with Gladstonian eyes, raised his hat and smiled. "I am in search of information about Roses, and Mr. Ess advised me to call." That was enough. Words of welcome, mixed with Roses, came in a stream. The old man eloquent might speak longer, but not more quickly between the pauses. "I suppose you grow a good many Roses, Mr. Walton, and know most of the best?" "Oh, no, not very many, only a few hundreds in different places; it's a good plan not to have them altogether if you can help it; and I get them from different places—different soils. For this particular soil—rather light—it doesn't do to get them from heavy soils, with a few strong roots and shoots like Willows; I draw them from poorer land, with smaller tops, but bushy bottoms. Always look at the roots. Get plenty of these, and tops will follow. 'No, don't take down names here, we will go in and do that; just time to see another garden before dark.' Twilight came, but the sermon went on until we entered the stately old house, and there found another rosarian—the light Rose of the home, who in her quiet, happy way puts you at ease at once, and you feel like one of the family—a gift which not all possess.

The repast over and to the library for the names of the Roses. "Ah! do you know this paper?" as the host laid his hand on a pile of Journals. "Oh, yes, very well, but think it's been just a little bit dull of late, and the heavy men seem to have been having their innings." Quick as thought came the response—"That's just what we say, but it is a bit better this week; they always get bowled out in time. We like good practice, but good reading as well, you know, and do not mind a little smart fencing, if it is smart." Feeling we were coming to close quarters the time seemed opportune for a direct question—"Might I ask, Mr. Walton, which of the writers you like best?" The reply was a staggerer. "Well, to be frank, I think I like the Farmer as well as any. I feel compelled to read him because it seems to come so easy, and I dabble just a little in his line in growing butter and eggs—real, I mean; and my wife likes the Daffodil of that name." "What, the Farmer! I should have thought you would have been all for Roses." "Yes, but the Rose men are either written out or lazy, but I can manage my own, and sometimes win—look at this cup! I am rather proud of it. Happy thought, shall we try it? It's nearly Christmas, you know." We tried it.

"By the way, Mr. Walton, do you ever write to the Journal; and if not, why not?" "Very little; editors, to tell you the truth, appear to be rather a funny lot. I once sent ten sheets of foolscap reckoning a few people up—judges, I mean—and about a quarter of it appeared. I asked for the rest back, and in about a month it came, 'with compliments.' Well, I will be level with them, I thought, so sent it to another paper; and that is the last I saw or heard of it. Not very encouraging, was it? But, by the way, do you ever write?" Those dark piercing eyes fixed me, and I had to confess that a while ago I did venture into the arena, but brought such a hurricane on my head, that I felt it prudent to retire. "Subject?" Oh! I just thought that some of our friends were getting a little too clever, and I happened to say so, and remind them of the triumphs of the men of the past: that is all.

"What! the 'Decadence of Gardening?'" A nod: and then a shout—"Nelly, come! here's the 'Emperor!'"—don't you remember that is what we called the man who a while ago threw a bomb into the camp and awakened the sleeping army, who rose against him in their wrath; but he is still alive. I am proud to meet your active Imperial Highness, and sorry you can't stay longer: the last train is 7.2: come again when you can." I shall, undoubtedly; and in the meantime "Ess and I" will discover they are found out, while I have tried to "make the best of them."—A TRAVELLER.

CYPRIPEDIUM CONCOLOR.

This is one of the prettiest of the section known to Orchid growers as the bellatulum group, and there are few more interesting or beautiful species in the genus. It is a native of Moulmein, and was first discovered by the recently deceased and distinguished traveller, the Rev. C. Parish, who, however, did not succeed in sending it home alive. This was about the year 1860, and a few years after Colonel Benson sent it home to Kew. In habit the plant is very dwarf, the leaves about 5 inches in length, deep green, with a greyish mottling above and purple beneath. The spikes rise about 6 inches, and carry, as a rule, a single bloom, though twin-flowered scapes are not uncommon.

The individual blossoms are upwards of 2½ inches across, the ground colour being very pale yellow. The number of spots about the base of the segment seems to make the specific name inapplicable, but some forms have few or no spots, and possibly from one of these it was named. A somewhat similar species is *C. niveum*, and for cultural purposes they may be bracketed. This was introduced to this country by Messrs. Veitch of Chelsea, who imported it in 1868 by chance among plants of *C. concolor*, or what was supposed to be this species. Both have been frequently imported since then by our principal nurserymen, and though hundreds of plants have been imported, only to flower for a time and then die, both are now well represented in collections.

Although hardly to be described as a difficult species to grow, *C. concolor* requires care and judgment beyond that necessary for the usual *Cypripediums* as represented by the *barbatum* and other groups, or the kinds, such as *longifolium* or *Schlimi*, that are referred to as *Selenipediums*. The roots of the Moulmein species are not so strong as those of the types with which I have contrasted them, consequently special preparation of the compost is needed. The generally accepted theory is that, as these kinds grow often on limestone rocks in their native habitat, this material is necessary to their well being under cultivation, and possibly there is not much fault to be found with this.

But it is certain that in many cases the plants thrive well without it, growing finely in good fibrous loam, a little peat, and chopped sphagnum with charcoal added. In the loam of which I am speaking there is a certain amount of lime, and this may, of course, have some bearing on the satisfactory condition of the plants. At any rate, limestone can do no harm in the compost, and I would not like to recommend anyone who had been successful by using it to discontinue it. It may be utilised in lieu of crocks as drainage, mixed with the compost or placed round the base of the plant after potting. I have seen this latter plan very successfully adopted, and I believe that it acts, to a certain extent, as a deterrent of the souring of the upper layers of compost so frequent when some descriptions of peat are used.

The roots do not apparently in most cases take hold of these loose lumps of stone, and there is an advantage in this, for they can be removed and replaced with fresh as often as necessary. When newly imported these plants are not usually very well rooted, and to get them to produce new tiers of roots must be the grower's first care. Obviously it is no use potting them in the usual way, and, unlike pseudo-bulbous kinds, they do not much relish being laid out on the stage in the way usually practised. They are best potted in limestone crocks or similar material, through which the water passes freely, keeping the base of the plant moist without wetting the foliage much.

Established plants must be very carefully repotted when this becomes necessary, and in turning them out of the old pots fracture of the roots should be avoided. Large pots are unnecessary; they hold too much compost, and this gets sour about the roots before they have time to take proper hold of it. Small or very weak plants may have the advantage of suspended pans, the proximity to light being of great importance. Lay the roots out carefully, retaining any chance bits of charcoal, crocks, or other material that may be still clinging to them. While not raising them much above the level of the pot or pan see that the crown of the plant is not deeply buried in compost.

After potting, water very moderately until the young roots are getting about the new material, but when again thoroughly established they may have a full supply. With regard to position in the house *C. concolor* dislikes sunshine, but on no account must it be placed in a dark corner. If it can be arranged they do splendidly suspended from

the roof, but these positions cannot always be spared for *Cypripediums*. The next best place is on an open stage over some moisture conducting material, such as rough coal ashes or finely broken spar or shingle. The aspect ought to be such that no direct sunlight reaches them at midday, as this is injurious to the foliage.

The heat of the East Indian house is most suitable, and a very moist atmosphere is congenial to rapid progress and freedom from insect pests. Red spider is perhaps the worst of these, and often attacks the under side of the leaves. Frequent spongings have to be resorted to if once these insects obtain a hold on the plants, but, as hinted, a moist atmosphere goes far to keep them in check. Other kinds needing this treatment are *C. bellatulum* and *C. Godefroyæ*, both rather variable species, and all are related to each other. These have proved themselves invaluable to the hybridist, such splendid hybrids as *C. Lawrebel*, *C. concolor-Lawri*, *C. microchilum* (not *macrochilum*), and the newer *C. Chapmani* and its variety *magnificum*, being a small number only of their progeny.—H. R. R.

ORCHID GROWING IN THE NORTH.

THE cultivation of Orchids in the North of England is becoming an increasingly favourite pursuit with those favoured residents of the country who have the means. The Orchid, as is well known, is a beautiful flowering plant which owes its Greek name to the peculiar shape of its root.

The South American Andes are, as compared with other parts of the world, the richest in useful species, but the number of Orchids growing wild in various parts of the world has of late years greatly decreased owing to the immense quantities that have been taken away to various countries. In South America, however, what has done more than anything else to reduce their numbers is the continual increase in the Coffee plantations, before the rapidly extending advance of which great zones of forest trees have been cut down lately, the trees on which the Orchids grow having thus had to make room for Coffee plantations. Few people imagine, when they see beautiful Orchids in luxuriant and gorgeous flower, how much trouble, work, and hardship have to be endured to secure them, to say nothing of the great expense.

Travelling in the Orchid-bearing districts of South America is extremely tedious and costly, and the transportation of the Orchid to Europe or North America from its native home by the collector is a difficult and uncertain process, which accounts to a great extent for the high cost of the Orchid. Orchids do not grow on trees plentifully as do fungi. To begin with, they never occur in large quantities, even where most plentiful, and after the plants, collected with so much trouble, have been carried long distances to the packing place strapped in bags on to the backs of mules, and taken across primitive narrow trails used by the Indians before the advent of the Spaniards, between rocks and trees and across rivers which have to be waded, often being delayed in course of transit for weeks together through having to wait till the low water in the streams is sufficiently enlarged in volume to enable a journey by canoe to be undertaken, only a limited number of Orchids survive.

It has only been after the lapse of a considerable time that practical knowledge of the culture and common sense treatment of the plants has led to their great popularity in this country, where most people who have good greenhouses grow them to a greater or less extent; and the North of England has of late become unusually famous for its Orchids through the enterprise of several Orchid growers who have paid special attention to these plants.

FANCY PRICES FOR FRAGILE PLANTS.

It used to be considered that Orchid growing was a harmless and amusing, if expensive, mania, somewhat after the style of stamp collecting, only more so. Now it is almost a separate, and that the leading, branch of gardening, professional or amateur. Orchids are cultivated in England from seeds, and seeing that it requires generally some eight or nine years, and about four years in the most quickly maturing plants, before they bloom, it will be easy to see how £5 or £10 for a very ordinary and unpretentious Orchid seedling may be a not uncommon price.

Mr. Fred. Scott of Preston, North Shields, has, for an unambitious amateur in a small way of growing, a large collection of fine Orchids, and the Rev. Mr. Burdon of Heddon House, Heddon-on-the-Wall, has some good specimens, including a few rare hybrids. The hybrids, many of which are exceedingly lovely and often very curious, naturally fetch the highest prices, and Mr. Norman Cookson of Oakwood, near Wylam, is one of the most distinguished growers in the country in this department, supplying a great many Orchid collectors in the South of England from his well-stocked Orchid houses. Not many days ago, for an Orchid in a pot of less diameter than a drinking tumbler, a South country Orchid grower was glad to pay Mr. Cookson 180 guineas for a hybrid; the unique rarity of the plant being, of course, what gave it such high value.

In all parts of the tropics, from Peru across America, Africa, and Asia to Siam, Orchid collecting is going on at such a rate that natural Orchids will soon be as rare as auks, and choice varieties of natural Orchids often bring very high prices; but at present the highest prices are given for rare hybrids produced in this country, one of the best known and most successful growers of which is Mr. Cookson, who has such an excellent collection that even a cursory examination of the contents of his Orchid houses would occupy the greater part of a day. — ("Newcastle Daily Chronicle.")

AS OF A DREAM (SEE PAGE 346, No. 2534).

I WISH YOU A HAPPY NEW YEAR!

PRAY do not suppose I am a Rip Van Winkle. "D., Deal" caused me to rub my eyes, however, and to become thoroughly awakened this morning (December 31st, *Journal of Horticulture* a day late) as I read his cursory mention of "Mr. Robt. Fenn," on page 616. He "believes" one thing there, and "thinks" another. Let me assure our "Chaplain" that I have not been napping. I have to consider the burning of the candle at both ends. I have no "living" resources to enable me to put in an appearance at head quarters nearly so often as I could wish—"Out of sight out of mind;" still, "D., Deal" need not have wounded me in the house of my friends by hurling "only an occasional contributor" at my head.

I have been told that one should not "write for the press for a longer period than ten years." Why, I had written reams in that time to the old *Cottage Gardener* before "D., Deal" had become connected with its pages. I seldom troubled our dead and gone respected Editors, however, until I found I had something to say which I thought might be beneficial for the public good in my particular way—which is not that of a rosarian. We must eat to live. My writings have always been devoted to practical work. Treatise upon treatise of mine can be shown in this periodical, which, combined for weight, would form a burden too heavy for your worthy contributor, "D., Deal," to bear, and all, remember, for the sheer love of trying to be helpful.

This subject, however, of the "longest contributor" has arisen quite often enough. I was in hopes it was buried and at rest. About this time two years a challenge was thrown down by a writer, in a learned article, inciting to decide this query. I took no further notice of it than to request a hope that you would let the matter sleep. Now we have got it rising again, and it is best to have it "laid." We shall not want "parson, bell, book, or candle," for I send you bodily the old type number to decide the phenomenon, where you can see that my first public writing in these pages began in 1850, No. 88, page 154, the subject Potatoes, and my last communication you will find in this eventful year of grace, No. 2534, page 345; and now I am awake, I will, if you agree, let you know what I have been doing in 1897 for horticulture since the above was written, merely throwing in here, *par parenthesis*, that I, as a Churchwarden, have taken a chief interest in ("Diamond Jubilee") reseating our St. Michael's Church. I hope "D., Deal," will not find fault with that.

They say that gratitude in its noblest sense is an unknown factor in politics. Then in the pursuit for improving the Cinderella of Nature—the Potato—how must I reckon? Is virtue to be its own reward? The desire to benefit mankind has caused me to experimentalise with Potatoes in earnest from the year 1837, and to bend the printers' backs in Fleet Street, E.C., at no very long intervals apart, from the date mentioned above. A propeller anent the "noble tuber," I take it, as having enthusiastically forced me on without any consideration of the cost, for if I had done this most assuredly the present generation of English Potatoes (some other might have done it but did not) would not be in existence. This same force, I take it, may have impelled Sir Walter Raleigh, who, happening to be in a quarter of the world where the *Solanum tuberosum* grew wild, saw the natives scratching the esculent from the earth as a pabulum for food, brought some to his home in Ireland, withal to benefit his fellow man. Whether Sir Walter was ever recompensed for his patriotism I know not, but his name and fame are hoist upon a Potato petard for ever.

Sixty years ago last spring I caused a portion of glebe meadow (see 2529, page 226), called the Hale End, at Stanton Lacy, Shropshire, to be trenched and fenced apart for experimental purposes, with the object of improving several of the then most popular varieties of Potatoes. I could not satisfy myself in this, for neglect the selecting of the best from the most promising stools for a year or so, and back to their deep eyed or other undesirable normal types they would inevitably go. I lost many years by beating about the bush in this way; but I have given you the history of these disappointments, also that of the unsatisfactory raising of varieties from Nature's promiscuous workings, that the word tautology is rising up with extended caution before my eyes.

As the years rolled on, however, cross-fertilisation came to aid me in 1857, and enabled me to resuscitate the esculent from the disease and decrepitude into which it had fallen. Your pages and the R.H.S. Fruit Committee (of which I was then a member) were soon made aware of these proceedings, for others to take up the tale, which have up to this time of day proved the means of securing for us the best Potato food in the world; and the Potato, I consider, takes a second place only to Wheat in perpetuity for human sustenance. I have for a long time thought, and I now express, that we can go no farther for excellence in this article for

food than what we have got, by further crossings with the wild *Solanum* tribe from Virginia, Peru, and those of the Andes. I will next, if allowed, hark back some two decades. — ROBT. FENN.

(To be continued.)

[What can we say to reconcile these two grand old men of the gardening world and the gardening press? We are bound to say that the "Pioneer" in Potato improvement (for such he is) was the first to commence writing in the "Cottage Gardener," but the "Chaplain" has written the most. With this record, which is founded on facts, let us hope that both the frisky young octogenarians will be satisfied. We have, however, a word or two of historic interest to add. Mr. Fenn has preserved all the letters he has received during his long and busy life. He has chestfuls of them, and knows where to find what he wants. Some of these letters we have seen, and will cite from one or two, because they are worth reading and have never hitherto been published.

We will first take the *last* letter that was written by the late genial Mr. G. W. Johnson (the founder of the "Cottage Gardener") to his old friend Mr. Fenn, as it settles the matter of the "oldest correspondent." The letter is dated January 2nd, 1879, and here it is—"You are the oldest of the 'Cottage Gardener's' recognised correspondents, your first contribution to its pages being in 1850; and I can truly say that no change has taken place in the twenty-nine years in the estimation in which you are held by G. W. J." This "first contribution" was a short note on soot and salt for Potatoes, written now forty-eight years ago.

We will now, as our old friend says, "hark back." In 1861 he seems to have been indulging in poetry; but the old chieftain was one too many for him, as on November 24th of that year he wrote to Mr. Fenn:—"Sir Godfrey Kneller always thought he ought to have been a soldier rather than a painter; and Liston, the comedian, as persistently maintained that tragedy was his forte; whether you think you excel in poetry rather than in prose I do not know, nor need I sit in judgment upon such an opinion, as we do not intend publishing any poetry this year."

This was rather a hard hit, but the genial old Editor had ready a solatium (and it indicates the date of no doubt the finest exhibit of seedling Potatoes, the result of careful cross fertilisation that the world had ever seen), for he goes on to remark—"What an interesting collection was yours at South Kensington last week. I never saw so large a collection of well-grown, perfect, and useful sized Potatoes. There was a cluster of ladies round it, loud in their praise, and it was long before their interest in it slackened." After that the "poet" could not very well complain by being told, in euphonious phrase, that his lines had gone into the W.P.B.

We have not quite done yet. The grafting of Potatoes has been from time to time adverted to as somewhat of a novelty, but here we find the chieftain, under date April 25th, 1872, writing to the "Pioneer"—"Thanks for your notes on the Potato grafting. They shall be fore horse in the next *J. of H.*" They were.

Now, for the last and not quite unseasonable citation, which is highly characteristic of the man who penned the original on December 19th, 1873. "To Mr. and Mrs. Fenn. To the latter I say, with Hudibras, 'Madam, I do, as is my duty, honour the shadow of your shoe tie.' To the former, 'May it never be your fate to lack Grape wine and sound Potatoes'; and to both I say heartily, 'May the coming Christmas and New Year be joyous.'"

To this may we add that during the period which has since elapsed Potatoes of his own raising and Grape wine of his own brewing have not been lacking by the gardener, farmer, and churchwarden of Sulhamstead; and still further may the hope be expressed—a hope in which many will join—that he and the "Chaplain" may be seen crossing swords dexterously, that never wound, after their next joyous Christmas and new year! —ED.]

SUCCESSFUL VIOLET CULTURE.

NOWHERE have I seen Violets in a more satisfactory condition than they are at this season at Bowden Hill House, the Wiltshire residence of H. J. Harris, Esq. Both the Russian and Neapolitan types are grown extensively to meet the demand for blooms, and Mr. W. Penton, the gardener, is to be congratulated upon his success with them.

A good type of The Czar is principally grown in the open, but a trial is to be given to the newer, longer stemmed, larger flowered varieties of more recent introduction. For pit and frame culture the popular Marie Louise is mostly grown, and when I saw these recently there were numbers of fine long stemmed blooms on the plants considerably above the average in quality, while the old Neapolitan was also doing well. To be able to pick twenty or more large bunches at a single gathering during the dull weather prevailing at the end of December, and that, too, without any forcing or undue weakening of the plants, conveys a good idea of what is going on at Bowden Hill House.

Mr. Penton believes in young stocks, planting newly rooted layers every spring, and the strong clumps resulting are not coddled in any way after they are moved into frames and pits—abundance of light and air best suiting them. The Russians are also all young plants, but they are larger than two-year-old plants are usually seen, and are all furnished with abundance of fresh, healthy leaves. Fresh soil, good attendance during hot weather, pure air, coupled with shade from tall trees during the hottest part of the day, are the conditions that suit Violets so well at Bowden Hill.—W. I.

WEATHER IN LONDON.—On Wednesday night last a heavy gale of rain and wind passed over the metropolis. On Thursday morning it was very showery, as were both Friday and Saturday. Sunday, though dull in the morning, cleared later, and the sun shone brightly. Monday and Tuesday were both foggy in the morning, but clear during the afternoon. Rain fell heavily on Wednesday.

WEATHER IN THE NORTH.—The close of the year past and the beginning of the opening one have been marked by almost uniformly dull weather, with a good deal of rain. There were 6° of frost on the morning of the 3rd, but thaw followed by midday, and the evening was raw and cold, and Tuesday morning very wet.—B. D., *S. Perthshire*.

ROYAL HORTICULTURAL SOCIETY.—The first meeting of the Royal Horticultural Society in 1898 will be held as usual in the Drill Hall, James Street, Westminster, on January 11th, 1 to 4 P.M. The four following notifications are also issued by the R.H.S.:—*Examination.*—The Society's annual examination in the principles and practice of horticulture will be held on Tuesday, April 5th, 1898. Candidates should send in their names not later than the 1st of March. A scholarship of £25 a year for two years is presented by G. W. Burrows, Esq., F.R.H.S., member of the Court of the Worshipful Company of Gardeners. *Meetings and Shows, 1898.*—The following are the dates fixed:—January 11th, February 8th, March 8th, 22nd, April 12th, 26th, May 10th, 25th, 26th, 27th (Temple Show), June 14th, 28th, July 12th, 26th, August 9th, 23rd, September 6th, 20th, 29th, 30th, October 1st (Fruit Show), October 11th, 25th, November 8th, 22nd, December 13th. *Notice of Meetings and Shows.*—A reminder of every show will be sent, in the week preceding, to any Fellow who will send to the R.H.S. Office, 117, Victoria Street, Westminster, S.W., twenty-two halfpenny postcards, ready addressed to himself. *Journal, Vol. XX., Pt. 3*, published March, 1897.—Any Fellow no longer requiring this number of the Journal would very greatly oblige by sending it to the Secretary, as it is already out of print.

"THE HORTICULTURAL DIRECTORY AND YEAR BOOK."—As the contents of the thirty-ninth issue of this annual are clearly set forth in advertisements, it is not necessary to repeat them here. A glance suffices to perceive their variety and usefulness. The changes of gardeners during the past year have been very numerous, and all that could be obtained in time for publication were inserted. The work consists of about 530 pages, and every gardener will like to have it handy for reference to various matters, including advertisements, and practically everything in demand in gardens. The price is the same as before, 1s., or by post 1s. 3d.

PEAR BEURRÉ RANCE.—"A very excellent late variety, good bearer, fine for walls," is what I read of this variety in a catalogue to hand, and certainly no better description need be given, for of all late Pears none gives us such all-round satisfaction. An old espalier-trained tree on a south aspect never fails to crop, and if the fruit is left on the tree to thoroughly develop, and not gathered (as is often the case, in stormy autumn weather) before it reaches that stage almost every fruit will ripen perfectly. A few introduced into slight warmth at intervals will keep up a supply, the flavour also being much improved by so doing. Its appearance, a dark green and russet, is sometimes against it, but where late Pears are appreciated this is easily overlooked.—R. P. R., *Liverpool*.

THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—A meeting of the above Society was held in the Parish Hall on the 28th ult., Mr. Geo. Picker in the chair. Mr. Geo. Giles, Hesslewood Gardens, read an interesting and practical paper on "Variegated Foliage Plants." The essayist described the methods of propagation and suitable modes of cultivation. There was a moderate attendance of members, and a good discussion followed. Mr. Blakey showed well flowered plants of *Cattleya Trianae* and *Cypripedium insigne* var., and Mr. Barker, gardener to W. P. Birkenshaw, Esq., brought a fine plant of *Laelia autumnalis* alba with twenty-two flowers, which received the Society's cultural certificate, also *Laelia anceps* Ashworthæ, *L. anceps* Protheroiana, tastefully arranged on the table with good Roman Hyacinths and Ferns. A vote of thanks to the essayist and Chairman terminated the meeting.

BOTANIST OF VICTORIA.—Mr. J. G. Luehman, for twenty-eight years the assistant of the late Baron von Mueller, succeeds him as Government Botanist of Victoria, and has now been placed in charge of the National Herbarium of Melbourne, with the title of Curator.

LIVERPOOL HORTICULTURAL ASSOCIATION.—The Committee of the above Association has arranged to hold the annual dinner and social evening for members and friends at the Adelphi Hotel, Lime Street, Liverpool, on Saturday, January 15th, at seven o'clock. Owing to the arrangements made for the dinner and excellent musical programme afterwards it is to be hoped that early application will be made for tickets.

A PLEA FOR THE PARKS.—We are accustomed to speak of urban parks as the lungs of cities, but the ideal park is more than a laboratory for purifying the air. It does more than offer an invitation to agreeable physical exercise and a change of mental occupation. Contact with and contemplation of natural scenery, especially of pastoral scenery, brings positive refreshment to the mind. Green pastures and still waters now, as in the days of the Hebrew poet, restore the soul. This, says an American writer, is a fundamental truth, and, therefore, it has profound practical importance.

GARDENING APPOINTMENTS.—Mr. C. Nicholson, for the past four years foreman at Rokeby Park Gardens, Barnard Castle, has been engaged as head gardener to Major Chichester Constable, Wycliffe Hall, Winston, Darlington. Mr. Charles Foster, who has been for some years gardener to M. S. Williams, Esq., Aberpergwm, has been appointed gardener to G. E. Jarvis, Esq., Doddington Hall, Lincolnshire. Mr. R. Bellerby, four and a half years foreman, Askham Grange Gardens, York, is appointed head gardener to Sir Theophilus Peel, Bart., Potterton Hall, Barwick-in-Elmet, Leeds. Mr. Richard Morse, late of Berkley House Gardens, Frome, has been appointed gardener to Captain Knatchbull, Babington, Bath.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—At a recent meeting of the Beckenham Horticultural Society a paper was read on the above subject which created considerable interest. A number of the members present, belonging to various sick and benefit societies, expressed regret that they were unaware of the special advantages of the Society before. It is to be regretted the working of a Society "by gardeners for gardeners" is not much more generally known. Anyone seeking information may obtain it from the Secretary, Mr. W. Collins, 9, Martindale Road, Balham, S.W. The question of admitting members to the benefits of the funds on one year's payment of subscriptions was discussed, and might advantageously receive the careful consideration of the Committee. The question was no doubt prompted by a desire to transfer, without fear of loss of sick benefit in the meantime. Gardeners desirous of making provision for old age, sickness, and death could not do better than transfer at once, especially if young, as the whole sum contributed (less actual annual working expenses) can be withdrawn at seventy years of age, or is paid out in full to the person nominated in case of death. Mr. E. Burge of Oakwood Gardens was accorded a hearty vote of thanks for his interesting and profitable paper.—M. WEBSTER.

CHURCHYARD BOTTOM WOOD.—The Parks and Open Spaces Committee of the London County Council, in a report which they have just issued, state that at the latter part of the year 1895 they had before them an application from the Hornsey Urban District Council for a contribution of £5000 towards the purchase money required for the acquisition of Churchyard Bottom Wood. At that time the Council could not legally make the contribution. Since then authority had been given by Parliament by the Highgate Woods Preservation Act, 1897, for the Council to assist in securing this land as a place of public recreation. They had been urged by the Commons Preservation Society, the Kyrle Society, the Metropolitan Public Gardens Association, and many residents in the district to recommend the Council to make a contribution of money towards acquiring the land, and, after mature consideration, they were of opinion that the Council should assist in the preservation of this desirable open space. It was true that the wood was outside the county of London, but it was so near as to be readily accessible to the inhabitants of the northern districts. And it was right that they should draw attention to the fact that, owing to the rapidity with which the area of the county was being covered with houses, it was already practically impossible to provide any more large open spaces in the central, northern, or eastern districts, except by the purchase of property at enormous cost; and it therefore seemed to them advisable that the Council should join with the other public bodies in preserving this wood for the public benefit. The Committee recommend a contribution by the Council of £2500.—("Garden.")

— DECEMBER WEATHER AT DRIFFIELD.—Mean temperature at 9 A.M. (corrected), 38.53°. Wet bulb, 37.3°. Mean maximum, 44.26°; mean minimum, 33.63°. Highest, 55.8° on the 16th; lowest, 21.0° on the 25th. Mean of maxima and minima, 38.94°. Mean radiation temperature on the grass, 29.03°; lowest, 19.0° on the 25th. Rainfall, 2.385 inches. Number of rainy days, fifteen. Greatest amount on one day, 0.83 inch on the 7th.—W. E. LOVEL, *Observer, York Road, Driffield*.

— THE WEATHER AT HODSOCK PRIORY IN DECEMBER.—Mean temperature, 39.7°. Maximum in screen, 58° on the 16th; minimum in screen, 21° on the 24th. Minimum on grass, 14.3° on the 25th. Sunshine twenty-four hours, or 10 per cent. of possible duration. Rainfall, 2.02 inches. Rain fell on seventeen days. Rainfall since 1st January, 22.55 inches; deficiency from average, 2.73. A mild month, with very little frost; rainfall normal; no snow. J. MALLENDER, *Workshop, Notts*.

— SUSSEX DECEMBER RAINFALL.—The total rainfall at Stonehurst, Ardingly, for December was 4.28 inches, being 1.54 inch above the average. The heaviest fall was 1.11 inch on the 7th (the only day an inch has been registered). Rain fell on fourteen days. The total for the year was 29.06 inches, which is just an inch short of the average. The maximum temperature was 53° on the 16th; the minimum, 25° on the 4th. Mean maximum, 44.07°; mean minimum, 34.27°. Mean temperature 39.17°, which is 1.36° above the average. A wet, stormy month. The new year has come in mild and more settled.—R. I.

— THE WEATHER LAST MONTH.—December gave little frost, although the temperature varied considerably. The wind was in a southerly direction on twenty-eight days. The total rainfall was 2.43 inches, which fell on nineteen days, and is 0.35 inch above the average for the month. The greatest daily fall was 0.58 inch on the 4th. Barometer (corrected and reduced), highest reading 30.690 inches on the 22nd at 9 A.M.; lowest, 28.916 inches at 9 P.M. on the 10th. Thermometers, highest in the shade 57° on the 16th and 17th, lowest 19° on the 23rd. Mean of daily maxima, 44.64°; mean of daily minima, 34.35°. Mean temperature of the month, 39.49°. Lowest on the grass, 16° on the 23rd; highest in the sun, 78° on the 30th. Mean of the earth at 3 feet, 42.58°. Total sunshine, 61 hours 25 minutes. There were eleven sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

— THE ROSARIAN'S YEAR BOOK.—The very neat and excellently printed annual for 1898 is received. It is edited by the veteran Rev. H. Honeywood D'Ombain, B.A., V.M.H., and contains articles on "The Rev. Joseph Pemberton" (with photograph), by the Editor. "Rose Shows; How they Strike an Observer," by Miss Muriel Grahame; "Yellow Roses," by the Rev. A. Foster Melliar; "The Rose and the National Rose Society," by the Editor; "A Chat about Roses," by Mr. A. Piper; "Roses in the South-West of Scotland," by the Rev. D. R. Williamson; "The Abolition of, and Substitutes for, the Treble Classes," by Mr. George Paul, V.M.H.; and "The Rose Weather of 1897," by Mr. Edward Mawley, Pres. R.M.S., and Hon. Sec. N.R.S. With such an array of talent the issue ought to be a good one, and this is what it seems to be. We hope to refer to it again, and at the present can only say the work is published by Bemrose & Sons, Ltd., London and Derby.

— ALLOTMENTS AND COTTAGE GARDENS IN SURREY.—The success which has attended the systematic judging of several allotments, cottage gardens, and local shows in Surrey, under the auspices of the County Council, has led the Technical Education Committee to issue a circular, of which we give the purport, as follows:—"This Committee feels that this system of judging 'is based on definite principles, under which every crop is appraised by independent officials,' and knows from several years' experience that it is thoroughly trusted by the workers. It has the further effect of not only stimulating to better work those who take part in the competition, but of eventually bringing them to compete with workers in other districts; hence the Committee is now prepared to offer the same advantages to every group of allotments, cottage gardens, and cottagers' shows in the county. Not only will the whole cost of judging be defrayed by this Committee without any expense to the Society, but certificates and prizes of books on gardening for special excellence will be awarded, and a lecture, discussion, or conference held in connection with the shows for the instruction of exhibitors. It is hoped that general county conferences will be held at intervals, and ultimately that a federation of horticultural societies for the industrial classes may be formed, working a general scheme approved by the best authorities on the subject, and aiming at a common standard of excellence." The officials of local societies that may be desirous of joining in the proposals are invited to communicate as soon as possible with H. Macan, Esq., M.A., County Hall, Kingston-on-Thames.

— ALTRINCHAM GARDENERS' SOCIETY.—We are informed that the result of two concerts held in Altrincham under the auspices of the Gardeners' Improvement Society showed a balance in hand of £39 5s., which sum has been divided between the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund.

— LA SEMAINE HORTICOLE.—With the issue of December 25th our Belgian contemporary reaches to the end of its first volume. Throughout the various numbers the pages have been occupied by brightly written notes and articles on all phases of horticulture as well as embellished with many illustrations. As might naturally be expected, considering the source whence our contemporary springs, the Orchid department is admirably conducted, and of never failing interest. To those of our readers who read French we commend "La Semaine Horticole."

— ESSAYS ON PRACTICAL FORESTRY.—We learn that the English Arboricultural Society offers medals for essays on the following subjects:—(1) The planting, maintenance, and management of a plantation for the first twenty-five years on (a) maiden land, (b) land previously planted. (2) The felling and barking of Oak or Larch timber, and the best modes of drying, housing and stacking, and preparing the bark for delivery to the tanneries. (3) The different methods adopted in the measurement of standing and felled timber, with diagrams if possible. (4) Original observations on any diseases attacking forest trees not yet thoroughly investigated. (5) The destruction of insects most injurious to forest trees not yet reported on, and coming under the notice of any individual member in England. (6) The results of any experiments having a practical bearing upon forestry. (7) The best method of reclaiming, draining, and replanting bog land, and the most suitable variety of trees to plant. The competition for the medals for the first two essays is limited to assistant foresters, but for the remaining essays the competition is open.

— AN AMERICAN CATALOGUE OF FRUITS.—A catalogue of fruits has recently been published by the Division of Pomology of the United States Department of Agriculture. This useful and valuable bulletin is the work of a committee of the American Pomological Society, of which Mr. T. T. Lyon was the chairman. Such species and varieties of fruits and nuts as are recommended for cultivation in the United States and in British America are arranged in three divisions:—Fruits mainly adapted to northern localities; sub-tropical and tropical fruits; native and introduced fruits and nuts grown in the open air. The entire region is, says a contemporary, divided into fifteen pomological districts, with primary reference to the influence of latitude, elevation, prevailing winds and oceanic and lacustrine exposures upon their adaptation to pomological pursuits. Comprehensive and carefully arranged tables show the size, form, colour, texture, flavour, quality, season, use and origin, besides the districts in which a particular fruit succeeds.

— EMIGRANTS' INFORMATION.—The January Circulars of the Emigrants' Information Office and the annual 1d. Handbooks show the present prospects of emigration. There is no demand for anyone in Canada at this season of the year, except domestic servants. In New South Wales there is no demand for more labour, and many workmen at Sydney are unable to find employment. Reports from Melbourne, Ballarat, and other towns and districts in Victoria state that there is no demand for more labour. The Vine-growing industry, for which Victoria is admirably suited by Nature, is now in a very depressed condition owing to the low prices offered for the wine and the general want of co-operation among the wine producers. In South Australia there is no demand for farm labourers. Queensland has been suffering for some time past from the tick plague, which has seriously damaged the cattle industry, and from drought, which has been prevalent throughout Australia. From these causes the demand for labour has been small, but the numerous railway and other works, which are now in progress, are helping to provide labourers with work. An agricultural college has been recently established under Government at Gatton, where students may learn farming for a small fee, and other steps are being taken to promote agricultural settlement. In agricultural districts there is a demand for good ploughmen and farm hands. The sugar industry is in a prosperous condition, and there are excellent openings for farmers with a little capital, after they have acquired some experience of the country. Large numbers of persons continue to arrive in Cape Colony from England and Australia, and many find much difficulty in getting work. In the case of any local demand arising, it is supplied by men from Johannesburg (Transvaal) and other parts of South Africa, where the labour market is overstocked. Speaking generally, there is at the present time no demand for anyone in the Colony except skilled mechanics.

HYBRID WINTER FLOWERING BEGONIAS.

By many persons Begonias are regarded solely as handsome summer-flowering plants suitable alike for the garden or the greenhouse. The kinds and varieties utilised for these purposes are certainly very beautiful, but we must not allow our appreciation of them to prevent us recognising the value of newer hybrids that flower from October onwards through the winter. Amongst these latter there are some charming flowers which, coming as they do

FIG. 2.—BEGONIA ENSIGN.

during the dullest months, are most acceptable. There are not hundreds or even dozens of forms, as in the case of those with tuberous roots, which flower in the summer. In fact, the numbers are extremely limited, but every one is good and worthy of a position in the warm greenhouse.

For how many valuable plants horticulturists are indebted to Messrs. J. Veitch & Sons, Ltd., of Chelsea it would be almost impossible to say, but certain it is that when they gave us the first of these hybrid winter-flowering Begonias they added to their laurels. This was in 1885, and since that time several have been added to the list. When Mr. Heal first started fertilising flowers of *B. socotrana* with pollen from flowers of tuberous-rooted varieties we cannot say, but we do know that when John Heal was exhibited before the Royal Horticultural Society on October 13th of the year named above, it was received with pleasure, and was pronounced by the *Journal of Horticulture* to be the forerunner of many valuable plants for winter use. Such has, indeed, proved to be the case, and those of to-day are immense improvements on the one of twelve years ago. The field is still open, and Mr. Heal is at work at Chelsea. Who, then, will venture to say what will eventually be attained to?

As is perfectly well known now, the foliage of John Heal is round and small, the numerous flowers being of rich rose colour, and the same can be said of the leaves of Adonis, which resulted from a cross between an orange coloured tuberous variety and John Heal, the former being the seed-bearing parent. The flowers of this, it will be remembered, are broad in the petal and rosy scarlet in colour, while the whole plant has a resemblance to *socotrana*. The third of marked beauty was named Winter Gem, which was staged at the Drill Hall on January 13th, 1891. In this case a crimson tuberous variety was the pollen and *B. socotrana* the seed parent. It is a charming

Begonia, the soft rose, circular flowers being very pleasing. All of these, it is now conceded, are admirable plants for the winter, and each received an award of merit from the R.H.S. The roots of the first and third named are, as with *B. socotrana*, in the form of bulbils.

It was in October of 1895 that Mrs. Heal was first exhibited, and it is undoubtedly the finest of the section. The large bright crimson flowers are of great substance, while the leaves have a texture and size not apparent in either of those previously adverted to. This and those that will be named subsequently had tuberous rooted varieties as the seed parent, and *socotrana* as pollen parent, or, in other words, they have sprung from the parents of John Heal reversed. Visitors to the Drill Hall will probably remember the basket of Mrs. Heal that was staged by the Chelsea firm at one of the latest 1897 meetings. The day was a dull one, but the flowers stood boldly above the bright green foliage, and made one of the most conspicuous exhibits in the show. Hitherto we have noted single flowers only, but on October 29th, 1895, a hybrid named Success was shown with semi-double flowers of good size. The plant is of branching habit, and the crimson flowers are produced with great freedom. It is a handsome Begonia, and is always much admired, though it is somewhat eclipsed by Mrs. Heal, which only preceded it at Westminster by a fortnight.

Following Success we had another double in 1896 that was called Ensign, and of which we give a woodcut (fig. 2). The colour of this is red, and the shapely plant is wonderfully floriferous. It is one of the best in cultivation so far. Exhibited on the same occasion (November 24th) was Myra, but not being in proper condition it failed in securing recognition from the Committee; nevertheless it is of great value, and is dissimilar from all the others in producing pendent flower scapes that give it a very graceful appearance. The colour is rosy lake. On November 23rd last we had Julius, with double salmon pink flowers. In habit this must be classed as one of the best. The last to be mentioned in our short list is Winter Cheer, for a representation of which see the illustration (fig. 3). This was staged on December 14th, and is of a rich rosy carmine colour, that will insure its becoming a favourite. Each of the six just named are tuberous-rooted, and every one has secured the award of merit, except in the instance already named.

The beauty of these plants and their utility entitle them to consideration from everyone who wishes the best possible display in the winter. Fortunately they do not demand anything very exceptional in the way of culture, for they grow splendidly in an intermediate temperature. An ordinary greenhouse is too cold for them, while a stove house is too warm. Propagation is easy, as plenty of cuttings can be secured which will root freely with ordinary care and attention. They need not occupy any great amount of space, as the plants will flower in as small as 3-inch pots, though of course larger plants require larger sizes.—H. W.

CELERY.

THIS forms one of the most important winter crops in every well-managed garden, for nearly everyone enjoys good Celery, either as a salad or when stewed as a vegetable. To have produce of the highest quality the cultivation of the plants must be of the best from first to last. I find the middle of February a good time to sow for the earliest crop. This is done thinly on a pan of loamy soil, covering with a quarter of an inch of the same finely sifted. The receptacles are then placed in a warm, moist atmosphere. White Gem is one of the best for a first crop, while Wright's Giant White, Solid White, Sulham Prize, and Standard Bearer can be depended on to produce large plants of the finest quality from the middle of August onwards.

A sowing of the larger kinds should be made during the first week in March, and as soon as the plants are large enough to handle they must be pricked into boxes or a frame properly prepared by treading hard on the bottom 6 inches of well decayed manure and spreading over this a couple of inches of fine soil.

The young plants may be dibbled in 4 inches apart up to the seed leaves. Given a good watering and the frames kept close for a few days, they will soon grow, and as they gain in size will require copious supplies of water, as it is quite as important that the plants shall not suffer any check from the want of water in the early stages as at any other period.

We like to prepare our trenches some weeks before planting, and prefer the single row system to two or more. Our trenches for the larger kinds are taken out 6 feet from centre to centre, each one being 16 inches wide and 1 foot in depth. This is nearly filled with manure, or failing manure decayed Oak leaves, and made firm by treading. On this is placed 3 inches of soil, and when planted is not much below the ground level. Some of the finest Celery we ever grew was from trenches filled with leaves, the latter having been saturated with sewage. In removing the plants from the frame or boxes care must be exercised, and the plants damaged as little as possible during the operation. Immediately after planting in the trenches they must receive a thorough watering, and if the weather is cloudy so much the better. The large heads sometimes seen at exhibitions, and which some people seem to consider unfit for consumption (although one is at a loss to know why this should be), are the outcome of marked attention as to thorough waterings, with at

times the judicious use of suitable stimulants either in the form of artificial manures or drainings from the cow house.

The dreaded Celery fly is almost sure to make its appearance on the plants, and must be kept in check by picking off all affected parts, while frequent dustings of soot will check its ravages and prove beneficial as a food. Celery intended for exhibiting must have plenty of room allowed for growing sturdily, 15 inches from plant to plant not being too much, while if double rows are preferred the trenches will need to be 20 inches in width, and the plants placed alternately in the rows. In addition to thorough drenchings of water whenever required, the plants will need to be examined to remove all sucker growths, as well as outer leaves as soon as they show signs of decay.

Earthing the plants should not be commenced until they have attained a considerable size, and pains must be taken in order that the work shall be properly done; a thorough soaking of water should be given the previous evening, and the stems allowed to become quite dry before any soil is placed about them, or they will be sure to decay. It will save time if two pairs of hands are set to the work, one holding together the leaves while the other places fine soil about them. Care is necessary in order to avoid adding too much soil at any one time, as experience has taught us that it is better to err on the side of too little than too much. The plants will require more soil to be added every nine or ten days until the final earthing, when the soil should be placed well up to the leaves, and the sides neatly finished, but not beaten with the spade, as the process does no good to the soil or the plants themselves.

For exhibition during August and September the best and easiest method of bleaching is accomplished by wrapping round the stems strong brown paper, strips cut about 9 inches in width being very suitable. This process should commence about a month before the exhibition with white varieties, but it is better to allow coloured Celery a week or ten days longer.—C. FOSTER.

THE HALL FOR HORTICULTURE.

WHAT IS THE REAL NEED?

I THINK that this may be described as a hardy deciduous perennial. It is continually starting up and making apparent growth, and from time to time various cultivators come forward to assure the world that they know how to make it grow faster; but somehow or other it refuses the treatment proposed for it, it dies down, and the inexperienced say, "Oh! the thing is dead." But no, after a while another expert comes forward, tells us he knows all about it, and that if we only listen to him the thing must succeed. Able financiers have propounded plans for it; would-be reformers, who like to see themselves "leading the way," have oracularly delivered their sentiments; but all to no purpose, the whole thing falls flat, and English horticulture, the first in the world, lays under the reproach of having no habitation which it can call its own. Let it not be supposed for a moment that I am going to propound any scheme. I rather want to clear the air of many things which seem to me to hinder its fulfilment.

I think the first thing for people to consider is what they really want. Some of the projects put forward seem as if the projectors wished to embrace every possible thing connected with horticulture—to abolish Covent Garden, to do away with the Royal Botanic, to deprive the Crystal Palace of its flower shows, and to wipe out the Royal Aquarium. I need hardly say that such plans as these are preposterous. But coming down to less ambitious schemes I would ask, What *do* people want? If they want a place where such large exhibitions as those of the National Rose Society and the National Chrysanthemum Society can be held, I would ask, Have they really considered what this means? It might be used three or four times in the year, but what is to be done with the building during the rest of the time? The expense of keeping it up will be no small thing, and require a considerable sum of money.

Then again we might ask, Where could such a building be placed? There is no place where ground could be had sufficient for the purpose in any central position, and that is indispensable; and it is tolerably certain that if the Crystal Palace could have remained where the first exhibition was held it would have been, instead of as now in financial difficulties, a thoroughly profitable concern. Was not the truth of this exemplified when the Royal Horticultural Society held its show at the Agricultural Hall, Islington? It was a grand exhibition, the place was full of beautiful plants and the only thing wanted was the visitors. The same cause has interfered with the conferences of the Society held at Chiswick. Valuable as they have been, few persons ventured to attend them, and those who did felt how unsuitable the place was for any purpose of that kind.

Dismissing, then, all such ambitious schemes I would ask, What is it that horticulturists really do need? They require a building where the Royal Horticultural Society could find really a home. A more suitable building, though not a much larger one than the Drill Hall, is required for the fortnightly exhibitions—one with better light and fewer cold currents of air; attached to this they require

a theatre or lecture room where the lectures could be delivered. Nothing could be more unsatisfactory than the present condition of things. A curtain is drawn across the upper end of the room; behind this the lecturer and his audience are assembled, while in the Hall itself the exhibition is going on. There is a continued shuffling of feet and conversation, and of course, were the attendance better, these evils would be considerably aggravated; and, altogether, it is not a very exhilarating task that the lecturer has to perform.

There should be rooms also where the various committees might meet, and where the ordinary committees of special societies might hold their gatherings. This would bring the societies themselves more into touch with the Royal, and would, I am sure, conduce to the well-being of such societies, and the Royal also. At present these special societies, with the exception of the Chrysanthemum Society, are indebted to the Horticultural Club for a convenient place in which to hold their meetings. If I take for instance the National Rose Society, I am sure its members would hail with satisfaction anything which would link them with the Royal. Here, of course, too, the Gardeners' Royal Benevolent and the Royal Gardeners' Orphan Fund, and any other benevolent society connected with horticulture, could hold their meetings, and, above all, the Council of the Royal would have a suitable place for itself, which I do not think it could be said

FIG. 3.—BEGONIA WINTER CHEER.

that it at present has. In such a building, too, the Lindley Library would find a suitable home.

Am I wrong, then, in saying that, dismissing more ambitious schemes, such a building as I have sketched out would comprise all that horticulturists need? As I said at the beginning, I have no plan to propose, and even this less ambitious scheme may be unattainable; but at any rate it will be something if horticulturists will agree upon what they really want when they talk about the Horticultural Hall.—D., Deal.

THE N.C.S. AND ITS SILENT SECRETARY.

INSTEAD of the Secretary of the N.C.S. meeting Mr. Moorman's powerful criticism (on page 605, December 23rd) of his former letter, he seems to be running after hares set up in another field. This is an ancient way of escaping from a tight corner. Cannot Mr. R. Dean any longer "face the music" of Mr. Moorman? What about the independent "autonomy" boast now? From data supplied by this "not rash" official, our great National Floral Society is still too weak to stand alone. The Aquarium crutch is a necessity. What if the Directors were to sell the whole concern? As business men surely they would not hesitate to do this if the terms were advantageous. In the case of such a change the N.C.S. must, according to Mr. R. Dean's showing, fall to the ground.

How any person can boast of the success of a number of years' "administration," when the position of a society (without its crutch) would be as deduced by Mr. Moorman from official figures, as stated on the page above cited, passes comprehension. Mr. R. Dean's silence in the face of that clear statement is very significant. It amounts in fact either to contemptuous indifference or acquiescence in the truth of the allegation that the Society which all the world thought so strong is in the pitiable plight of bondsman to a speculative organisation known as an "Aquarium," but really a centre of boxing, music, dogs, and mountebankism, in fact of anything not meretricious that will "draw" the public and produce dividends. It is the obvious duty of the Directors to do the best they can for the shareholders, and as a place of amusement nothing need be said against it. Many of us who object to the place for a Chrysanthemum show do so only because it is for such purpose, and, of late years especially, so utterly unsuitable.

When the shows were first held there, the floor space in the main hall was occupied in a very different manner than has now become the custom. The competitive classes could then be examined as arranged on long rows of tables in the best light available, and no strong objections were made so long as the Aquarium Company was felt to be doing all that could be reasonably expected of it for the Society by which it profited. It is true that Mr. R. Dean, as counsel for the Aquarium Company, does not admit of such profits falling to its share; but does any sane business man believe that the Company would afford space for the N.C.S. shows, however huddled the exhibits, year after year, if no profits accrued? The Directors would not be worthy of their seats at the Board if that were so. They regard the N.C.S. and its followers as a means of income, and if at the time of their shows they can make more of the space than devoting it to competitive exhibits of Chrysanthemums, they make it, and these are sent "upstairs," and any dingy place is thought to be good enough for them.

If Mr. Moorman's statement of the case cannot be controverted, then must his allegations not only be regarded as proved, but also it may be inferred that the Directors of the Aquarium know their power over the Society, and leave its Committee to take what is offered of space, and make the best of it. Whether the "best" is made is another matter, so far as regards the disposition of plants and blooms. Some persons are of opinion that the N.C.S. was not established for providing space for large displays of vegetables, mainly in the form of trade advertisements; and if it be true that some exhibitors buy this space on special, not to say exclusive terms, then there need not be much surprise that the Aquarium people do not put themselves to any great inconvenience in regard to exhibits that come more legitimately within the sphere of the N.C.S.

Another point in Mr. Moorman's unanswered, if not unanswerable, letter (December 23rd) that Mr. R. Dean ought to meet frankly is that he "alone" (page 554, December 9th) is cognisant of the whole of the assistance that the N.C.S. derives from the Aquarium Company. This is his own statement, and has created some surprise. He has not faced Mr. Moorman's comments on the matter, but has preferred to run away. Has any official the right to keep to himself any information he possesses relative to the management of the Society of which he is Secretary (paid or otherwise), and thus leave the Committee in ignorance of the whole facts bearing on the policy for which its members, severally and individually, are responsible? Is it fair even to the Aquarium Company that the full extent of its assistance to the N.C.S. should not be made known? The Chairman of the Committee surely ought to be consulted on everything, and be made acquainted with all that is done for the N.C.S. He is regarded as a just and prudent man, and is not the less respected for his uniform courtesy to all his colleagues, and his innate modesty in demeanour contributes to his strength. Very much will depend on him in not only maintaining but increasing the *status* of the N.C.S. which its Secretary has been instrumental in showing is buttressed (and in his opinion hopelessly) by the R.A.C.

But to return to the tactics of Mr. R. Dean in ignoring Mr. Moorman's last and most important communication. If this is done by way of silencing an opponent who has done what he obviously feels to be his duty in the ultimate interests of the N.C.S. the "move" may or may not be successful; but as the matter stands Mr. Moorman's statements may be

taken by distant members as so weak as not to be worthy of notice, and it is for him to consider whether he is content that this should be so. Has he nothing more to say?—AN OLD MEMBER.

THE N.C.S.—WHY NOT THE AGRICULTURAL HALL OR EARL'S COURT?

AT last not one, but two possible alternatives to the Westminster Aquarium have been suggested for the shows of the National Chrysanthemum Society by "An Exhibitor." This correspondent knows very well if any building is within a shilling cab fare from most of the chief railway termini that this meets all the requirements for the conveyance of produce. In that respect the Agricultural Hall is quite as convenient for the majority of exhibitors as the Aquarium is, and as to visitors they can get for 2d. bus or tram fares as easily to one place as the other.

If the Agricultural Hall could be had on reasonable terms for a November show, and anything like the usual prizes were offered, an exhibition could be arranged which, from a spectacular point of view, has not yet been seen anywhere, and which could not be approached by the Aquarium. There would also be space in the far greater building for all the people who attend the one in Westminster and many more, who could inspect the exhibits in comfort, while there would be no difficulty on the score of refreshments and social gatherings to those who attach importance to them.

It should be remembered, too, that the great populations in the eastern and northern districts of London have learned to love Chrysanthemums above all other flowers through attending the shows provided by the County Council in the public parks. They stream to those shows in thousands, and at the Victoria Park show provided by Mr. Moorman the number of visitors is far greater than attend the four shows of the Aquarium to see the Chrysanthemums.

But are four shows needed? Would it not be better to concentrate resources on *one*? A really great three or four days' show in a building suitable to its display would command success anywhere in London. Minor shows amount to a frittering away of resources. So far as the work of the N.C.S. is concerned all that is needed, apart from one magnificent show, is a room for the Floral Committee to examine new varieties at intervals throughout the season.

It may be said against the Agricultural Hall that a summer show of the R.H.S. was once held there, and that visitors did not "come in their thousands," and that, therefore, the Hall has been proved unsuitable for the purposes of a flower show. It has never been proved unsuitable for a Chrysanthemum show.

In some of the greatest provincial cities and towns—such as Liverpool, Birmingham, Leeds, Hull, and others—spring and summer shows have drained societies dry, whereas autumn shows have replenished their coffers. Spring and summer shows have been held at the Westminster Aquarium, but failed to attract the public in paying numbers, and the shows were abandoned. The exact opposite has been the case with at least the chief autumn shows of the N.C.S., and no doubt the Aquarium Company have benefited by the series to the tune of some thousands of pounds, while we are now startled by the intelligence that the Society cannot meet the demands of a show of its own. It is a humiliating disclosure.

Are there no gentlemen strong and earnest enough, with time at their disposal, who will try and place the Society on a firmer sounder basis, and higher plane? and if they succeed, as able zealous men do succeed, immortalise themselves as public floral benefactors? The working community cannot do this; independent men are wanted to take the lead. There are such who are dissatisfied enough with the Aquarium, and who could, if they would, do splendid work in extricating the N.C.S. from its present subservient position.

The summer shows at Earl's Court were not failures, and it is reasonable to suppose that a great November show would be a still greater success. The London public have got to know their way to that great popular rendezvous, and there are railway stations on all sides of it. It is easier of access than the Aquarium, but not perhaps so handy for exhibitors as this centre and the Agricultural Hall, because for Earl's Court there would be the necessity in many cases of "transhipments" of exhibits from main lines to the "Underground" for reaching the destination. This, however, would not be a formidable impediment. Offer good prizes and the best produce will find them, while thousands of persons would attend a great Chrysanthemum show in a building in which it could be seen and enjoyed.

Has any really serious attempt been made to find another place than the Aquarium for the great show of the N.C.S., and if not, why not? The desire has been loudly enough expressed, and the Secretary does not seem able to find a solitary supporter in singing the praises of the Aquarium. Evidently if any change should be made another secretary would have to be found. Young Mr. Holmes is said to give good help now, and, with the assistance of practical committeemen, he might become a creditable successor to his lamented father, who did so much in raising the N.C.S. to a commanding position.—ANOTHER EXHIBITOR.

THE N.C.S.—WHY NOT A PROVINCIAL NATIONAL?

I AM surprised that no one has suggested that the N.C.S. should hold at least some of its shows in the provinces in the way that the N.R.S. and other special horticultural societies do. I have heard it hinted that a Midland "National" Chrysanthemum Society is likely to be formed upon the lines, but improved, of the N.C.S. The late Mr. R. Owen frequently advocated such a society. I have no wish to disparage the good that the N.C.S. may do, but after all has been said and done, the N.C.S. does

not really lead. Larger shows, as far as Chrysanthemums alone are concerned, are held in the provinces, and other societies offer larger prizes, and have, according to the Secretary of the N.C.S., a much better attendance, also, what is still of further importance, are self-supporting.

It is true that other societies have not the run of the daily and horticultural press the same as the N.C.S. This has a great deal to do with the standing of this Society. Then as to the affiliation of provincial societies with the "National." What, I ask, do they gain by it? and where is the assistance which Mr. Dean mentions as rendered to them in a letter of his in a former number of the Journal?

The N.C.S. is only "national" in name, and were it not for the constant flow of novelties and the enterprise of provincial societies, the N.C.S. would dwindle away. Without in any way wishing to become personal, I ask anyone to analyse the Committee of the N.C.S., and it will be found that its members reside either in London or within a few miles radius, and whilst admitting that some are good growers, there are a large number who are not, and never have been, although they are capital "penmen." Surely there would be no serious difficulty in the way of a Midland society, and if care be taken in the selection of the committee, certificates awarded by this society would have equal weight, or more, than those of the N.C.S. Now that the Birmingham Society has migrated, or rather its exhibition has, to a splendid building, why does not its executive consider the matter of a great national society in the centre of England?—PROVINCIAL.

LATE WHITE CHRYSANTHEMUM ELAINE SQUELCH.

ONE of the best late white Chrysanthemums is a seedling named Elaine Squelch, which I have recently seen at Boxhurst, Dorking, raised by Mr. Squelch. The plants are dwarf; flowers of good substance, petals rather broad, and pure ivory white. It is a great addition to the late white varieties, and will be useful for market purposes.—C. B., Kingston.

WINTER FLOWERS.

IT is bleak and dreary outside in the garden at the present time, but within the greenhouse it is so bright, cheery, and warm that it is like stepping suddenly from winter into summer; a delicious fragrance, too, fills the air, for there is a row of Roman Hyacinths in full flower. Plants which give us flowers in November and December are especially precious. Chrysanthemums are our chief resource, and I have been more than ever pleased this year with mine; but to make a house of any size look gay you must have small as well as large plants, and except under very careful treatment Chrysanthemums are apt to become "leggy."

I know of no plant so pure and sweet as the Roman Hyacinth, unless it be another bulb, the Paper White Narcissus. But this latter is not nearly so free-flowering as the Hyacinth. The double Roman Narcissus has behaved unusually well with me this year in the matter of flowering. Nearly every bulb is throwing up a spike. It has had exactly the same treatment as the Paper White, but is some weeks in advance of it. The fragrance is delicious, but the flower itself, like a great many other double flowers, is wanting in grace and beauty. If you wish to secure an abundance of sweet white flowers in November and December obtain the Roman Hyacinth.

I have never succeeded so well with the Richardias as this year. They were planted out in the kitchen garden, and then produced so many of their large white spathes that I half sighed as I gathered them to think that in the winter they would be exhausted, and we should have no more; but it has not been so. They have been arranged in large pots on a back shelf in the vinery, and there they have continued producing their spathes. In a controversy, therefore, about what is the best to do with the Richardias in summer, I should decidedly give my vote in favour of the planting-out; but I fancy in most seasons a trench would be of great service in keeping sufficient water about the roots; moreover, I do not think that the situation should be a warm one, but only half exposed to the sun. One very great advantage of the Richardia is that the spathes last so long in the room. In these days of room decoration, when large stately growing plants are so useful for that purpose, few are more welcome than the Richardia. At this time of the year to have the dark glossy leaves and tongue-shaped spathes ornamenting some bright corner in the drawing-room is indeed gratifying.

Double Primulas are also early winter flowers almost invaluable. The double fringed are nearly as pretty as single flowers, with the great advantage of standing so well after being cut. The old Double White seems to be more floriferous than the large and beautifully fringed specimens of more recent days. But the latter make up for quantity by the richness and fulness of a single truss. I find that they like deep potting, and that they are less likely to damp-off when so treated than when the rootstock is above ground, and the plant consequently unsteady. With a very little care they can be made to flower during the whole winter. Two words, I should say, give the chief requisites for successful cultivation—viz., warmth and air. Cyclamens require much less of the latter; in fact, I never succeeded so well with any as with some which I shut up in a cold frame in early spring and kept close during the hottest days of April. They came on quickly and flowered, as Cyclamen will flower when well treated, till they became a mass of starry blossoms. But they are sulky, and the special aversion of my factotum, who declares he can make nothing of them. He begged me to buy a packet of seed a few years ago, because he thought he could do better with younger corms. But it was only the same thing again. I have taken them in hand myself now, and

I hope to have Cyclamens again this winter. I am sure one great secret is to give them proper treatment in summer, and I believe that treatment is to plant them out in a sunny position and to give abundance of water.

I must not forget to mention as a first-rate plant for this season Abutilon Boule de Neige. It flowers freely, is easily grown, and has good foliage. The only quality about it at all objectionable is that it does not seem to like a visit to the drawing-room. It is essentially a conservatory plant. Perhaps some would find fault with it for not having any scent; but the globe-shaped bells are lovely enough to do without that. Give this Abutilon plenty of water and good heat and you will have abundance of flowers. A few days ago the border between the white cloth outside and the satin centre of a large dinner table was composed of flowers of *Luculia gratissima*. This made a lovely border, and the scent was quite delicious. It is an old-fashioned plant, but that only makes it the more valuable.—P.

HARDY SHRUBS FOR FORCING.

DURING winter and spring, when outside flowers are over and Chrysanthemums are past, the inside resources of most establishments are strained to their utmost to meet the demand for cut flowers and flowering decorative plants. In those gardens where a sufficient number of reserve houses and pits are at hand the demand can, to a certain extent, be met by large quantities—Ericas, Genistas, Cyclamen, Primulas, Carnations, Cinerarias, and others being grown; but even then forcing has to be resorted to. In those establishments, however, and they are many, where reserve houses are limited, forcing becomes a necessity. Bulbous plants are possibly most in favour, but these do not wholly fill the gap made by the dearth of flowers outside, so hardy shrubs are called into requisition. It is my intention to enumerate those most suitable for the purpose. Several—such as the Rhododendron, Lilac, and *Deutzia gracilis*—are old favourites, but there are many others which have equal calls on our attention, but are rarely seen.

Commencing with *Cytisus*, there are several species which can be admitted to the greenhouse for early spring work. The best are *C. biflorus*, *præcox*, *scoparius*, *Andreanus*, *pendulus*, and *albus*. It is best to grow stocks of these for the purpose of forcing, and keep them in pots, as they do not lift very well. They give little trouble, and after two or three years, if they begin to deteriorate, they should be thrown away and young ones brought on. *C. biflorus* and *scoparius* should be grown from seeds, also *albus* if desired; but all flower better if grown from cuttings or grafts. The latter method is preferable, as good plants can be had quicker. *C. scoparius* or the Laburnum can be used as stocks. *C. scoparius pendulus* makes an effective plant when grafted on tall Laburnum stems, the long, slender growths having a pleasing effect when covered with bright golden blossoms.

Several species of *Prunus* are acceptable. The one most frequently forced is *P. japonica*, and it is a beautiful plant, the long growths being covered with pure double white blossoms. The Chinese *P. triloba* is worthy of note, as also is the pretty pink flowered *P. nana*, from South-Russia. Dwarf plants of *P. cerasifera atropurpurea*, or, as it is commonly called, *P. Pissardi*, are worth attention, the bronze leaves and white flowers being pleasing. Double flowered Cherries may also be used, *Prunus cerasus Rhexi fl.-pl.* and *serrulata* being the best. Short-stemmed bushy plants will be found most serviceable.

The genus *Pyrus* offers contributions in various coloured varieties of *P. japonica*, the scarlet flowered *Maulei*, the small flowered and scented *arbutifolia*, and *nigra*, also *Malus floribunda*. *Amelanchier canadensis* is specially worthy of notice; it forces well, and dwarf bushy plants thickly covered with racemes of pure white blossoms make a perfect picture. *Choisya ternata*, a fairly well known evergreen shrub which produces good sized heads of sweetly scented white flowers, is indispensable, as also is *Viburnum Tinus*.

A number of Lilacs can be used. The varieties of *Syringa vulgaris* are usually selected for this work. The dwarf growing and sweetly scented *S. persica* is not often seen, but forces well, and is in every way a desirable shrub. Good plants of *Corylopsis spicata*, when covered with their catkin-like yellow flowers, are attractive. Among *Deutzias* we find several which are suitable, such as *D. gracilis*, *crenata*, and *Lemoinei*.

The rich genus *Magnolia* provides several very good subjects in the white *M. conspicua*, *stellata*, and the purplish *obovata*. They force well, are striking when in flower, and last a considerable time. *Spiræas confusa*, *Thunbergi*, and *arguta*, all producing neat white blossoms, are useful for variety. *Kerria japonica*, with the double-flowered form, produces large quantities of bright yellow flowers. *Hydrangea paniculata*, with its large terminal panicles of sterile flowers, is well known as a good plant for this work. The sterile form of *Viburnum Opulus* can be satisfactorily used, as also can *Philadelphus Lemoinei*. The tree *Pæony*, *Pæonia Montan*, of which a large number of garden varieties can be had, should be used in quantity, the flowers being both large and handsome. Roses, particularly the Tea section, are always acceptable, and are easily managed. No establishment should be without a selection of the best for spring work.

The genus *Rhododendron* produces many beautiful forms for the purpose. Of the earlier flowering varieties of the evergreen section, such as Cunningham's White, *altaclarensis*, *Nobleanum*, *præcox*, and Rosy Bell, are the best to force. Of the deciduous forms *R. sinense* (*Azalea molle*) and *R. flavum* (*Azalea pontica*), with their respective varieties, are the most useful. *Daphne Mezereum* can be had in midwinter with little forcing,

and is worth a place if only for its perfume. Forsythias should be represented; suspensa is perhaps most useful, but viridissima and intermedia are also of service.

For hardy shrubs strong forcing is objectionable, better results being obtained by gentle work. After flowering the plants should be pruned, and stood in a cold house to harden before being put outside. About May all—with the exception of Roses and Cytisus—should be planted in the nursery. In places where forcing is carried on to a large extent it is preferable to grow shrubs for the purpose, and keep young plants growing to take the place of older ones, which deteriorate after several years' work. If taken good care of after flowering many will be good enough to force for several successive years, and with an occasional season's rest will last for a number of years. It is unwise to keep plants in pots all the year round; if this is done they will soon be worthless.—W. D.

EELWORM DESTRUCTION.

"THE clear remarks about soluble phenyle and its composition" (page 570), satisfactory as they may be to Mr. W. Dyke, give no idea of its chemical elements, and consequently furnish no data as to contained plant nutrition or otherwise. We are told, however, that it has "some theoretical manurial value, as it contains 1 per cent. of potash." What of the remaining 4 per cent. constituent of the softsoap? And what becomes of the "nitrogen in creosote" when treated with the 5 per cent. of caustic soda? Is it not made suitable for plant nutrition? Let the answer be clear and supported by practice.

So much for the "theoretical" as compared with the practical manurial value of soluble phenyle. In the latter respect Miss E. A. Ormerod first notified the fact, if I remember rightly, in 1878, when alluding to the destruction of Carrot fly maggot, or larvæ of *Psila rosæ*, as follows:—"Copious watering, with an occasional application of dilute soluble phenyle, stopped the attack, and threw the Carrots into vigorous growth." The creosote must have yielded its nitrogen, and the whole soluble article speedily converted into plant food. On those grounds, and the verifications of experience, soluble phenyle was advised as giving "value for outlay as a manure," and because, in practice, "it acts as a fertiliser." Truly, "there is something wrong somewhere."

In the second paragraph of Mr. W. Dyke's article (page 596) I am pleased to notice his acquiescing in the potency of lime and kainit as eelwormicides, and that he so highly approves of "boiling water" as to advise its use "to kill any eelworm living." But I must direct his attention to the statement in 1896 of Cucumber and Tomato root-knot eelworm being unknown, according to his dictum, as an outdoor infestation in this country, and of its succumbing when the soil was exposed to the weather for some time. In 1897, "any" eelworm may be in turf, but that he submitted last year was root-knot eelworm (*Heterodera radicolica*), not the blunt root-stem eelworm (*Tylenchus obtusus*), page 597.

I may also congratulate Mr. W. Dyke on withdrawing from the overshadowing wings of "authorities" and of "other persons' experiences," and giving us something for which he may himself be held responsible. Thus we get at the kainit and basic slag treatment—practically the same as the first and lime. But even then he does not see the difference between treating plantless soil left for weeks and that of plants in the heyday of growth. An ounce of kainit per gallon of water is as much as I have found Cucumber plants to bear without injury to the roots, and 2 ozs. per gallon of water a maximum dose for Tomatoes. What then becomes of the 12 ozs. of kainit to a gallon of water, and wherein exists the analogy? Try it, and then write.

Turu we now to "unkillable and mysterious" eelworm, for which "kainit and lime are the only palliatives recognised by scientific experts as of any practical use and application" (page 571). Very well, the any and all eelworms found in England live in its surface soil, there sustained by organic matter, either in a dead or living state. Taking into purview the whole surface area—arable, pasture, and other land, the average depth of the vegetable mould does not exceed 4 inches. This, treated with, in round figures, 4 ozs. of kainit per square yard, 7 lbs. per rod, 10 cwt. per acre, in the autumn or early in spring, when moist, but with a prospect of fair weather for a time, becomes freed from eelworm, contingent on its containing a fair proportion of lime. This, however, usually does not exist to a sufficient amount in the surface soil for the essential forming of chloride of lime, hence we must supply this in conjunction with the kainit, and ordinarily as much—4 ozs. per square yard, 7 lbs. per rod, 10 cwt. per acre.

By using basic cinder phosphate with the kainit instead of lime we get about 5 cwt. of the latter, which acts similarly to that specially prepared, and in most cases effectively in destroying eelworm. But in Nature, and still more in cultivation, the surface soil varies considerably in depth, hence no particular data can be given as applicable to all cases. The deduction, however, at which I have arrived, after several years' observations and experiments, is, that for eelworm infestation, the kainit should be used in the proportion of one to three of lime, or 1 oz. kainit and 3 ozs. lime per square yard to each 1 inch depth of rich vegetable, worked, or prepared soil. The former has 4 to 6 inches depth of soil, let them use 4 to 6 ozs. of kainit and 12 to 18 ozs. of lime per square yard. Double the amounts quoted will serve for land under spade or fork culture, the 8 to 12 inches depth of soil respectively, and when dealing with calcareous or light land, exercise discriminative judgment or "brains."

The chances of handling the £50,000 are thus extremely small, for nearly everything depends for success on the avoidance of cultural errors

and mistakes, and in apportioning the amounts of kainit and of lime as befits the diversities of soils and of the various requirements of different crops, thus rendering universal preventives and remedies practically inapplicable to all circumstances. However, there can be no reason but indifference why foreign growers should ease consumers of garden and farm produce in this country of the cash so much needed by the home growers. This I consider far more important in respect of prevention and remedy than eelworm destruction may be to foreign growers. The difference between a bogus £50,000 and a substantial £50,000,000 a year, worse than lost to British farmers and gardeners, is that of the shadow and the substance. Scientific men should be exact, and not indulge in random figures, and it is not less important that experimentalists should proceed with caution and exactitude.—G. ABBEY.

EELWORMS sometimes attack the roots of Cyclamen, causing them to swell abnormally, and having the effect of completely paralysing their action. For this reason the pans containing the seed, and the young plants later on, ought never to be placed in near proximity to Cucumbers, Tomatoes, or other plants, the roots of which are liable to be infested with this nematode. The remedy is Little's soluble phenyle, diluted freely, a wineglassful, or 2 ozs. as measured by an 8 oz. medicine bottle, proving sufficient for 3 gallons of water. This applied occasionally instead of clear water, proves destructive to the eelworm and stimulates rather than retards the growth of the plants.—W. IGGULDEN (*Journal of the Royal Horticultural Society*, December, 1897, page 270).

[Yes; there is evidently "something wrong somewhere," either in the material or its application. One person kills his plants with soluble phenyle; another does not, nor eelworm either, and so has done with it; a third, if not a fourth, has no belief in its manurial properties; and then comes the gardener with the largest experience as a cultivator of all of them (not including Mr. Abbey)—a grower of plants and produce for market, and closely watchful of his outlay and its returns, who finds investment in soluble phenyle profitable, inasmuch as it is "destructive to the eelworm and stimulates the growth" of his tender rooted Cyclamens. It is evident that Mr. Iggulden has found a "palliative other than kainit and lime," and we suspect he would hesitate to apply the eelworm-killing quantities of these to the Cyclamens which he grows so luxuriantly. The problem of one person killing plants and another curing them is still unsolved, and the less of bantering or boasting on either side the better.]

FORCING RHUBARB.

THE rich, luscious, and tender stalks of gently forced Rhubarb are greatly appreciated at the present time and during the next two or three months. Forcing in December is, under the best conditions, rather slow. The roots do not respond so readily to the stimulus of heat while the days are shortening, but now, the new year having come, and the days have commenced to lengthen, forcing becomes less and less difficult. A steady regular temperature of 55° to 65° proves quite strong enough to induce growth.

Rhubarb may be forced in any warm position, but the roots must be kept moist. In a warm but arid atmosphere it will be best to surround the roots with soil in addition to that adhering to them when dug up. With frequent watering and syringing of the crowns there will be enough moisture to incite the production of plenty of white fibrous roots with feeding root hairs. On the other hand, when the atmosphere is sufficiently moist and the temperature high enough, the roots will only require frequent syringings, supplemented by one or two good waterings as may appear necessary. Positions affording conditions of semi-darkness are best for forcing Rhubarb, but it will succeed in full darkness.

In selecting roots for forcing, let them be not less than two years old. Those which have grown vigorously and been undisturbed for several years are the best. Roots are generally considered to force better if lifted some time prior to taking in for forcing, leaving them exposed to cold weather and frost, which serves the purpose of effectually checking them, after which growth seems to recommence better. Secure the roots as large as possible, only reducing them to a portable size by cutting the large fleshy roots down with a sharp spade as they are dug up. A few taken in every fortnight will usually meet the demand.

The warmest and most favourable corners should be chosen for roots giving the earliest supplies. The later, needing less stimulation, may be accommodated where the heat is not strong. Failing the floor or under the staging of a warm house, a warm, dark cellar can be utilised, though possibly the temperature may not be sufficiently high for an early crop. Roots can be placed in boxes or tubs and covered with others of the same size inverted. The advantage of these portable receptacles are that they can be placed in positions where bottom heat is available, as, for instance, over hot-water pipes, or in their immediate vicinity. Always, in these cases, surround the roots with soil, so that constant moisture is present about them, and not evaporated as soon as given. In March a number of roots in the open ground may be covered with inverted tubs, or large, deep drain pipes. In this manner an early supply of delicious, well coloured stalks may be secured before the first natural supplies from the open are ready.

Rhubarb can also be forced early without lifting, provided fermenting material can be obtained. The crowns should first be covered with boxes or tubs, having moveable tops for readiness in gaining access to the produce. Round these pack the fermenting material, which may consist of equal parts of stable manure and leaves. Carry the material over

the tops of the receptacles, but not to any great depth. Should fermentation be too rapid steady the heat by treading the material well, or reducing the height of the heap. It is very important that the forcing should be steady, or the stalks will be of bad flavour and colour. Hawke's Champagne and Early Red are the best for early forcing, and Victoria for later.

After being lifted and forced Rhubarb roots are not worth replanting, and the stock must be kept up by lifting and dividing unforced roots, deeply digging and well manuring the ground before doing so. Plant 3 feet apart every way before growth commences.—E. D. S.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

WE are requested to state that Arthur W. Sutton, Esq., of Reading, will preside at the annual friendly supper of members and friends of this Institution to be held at Simpson's, 101, Strand, London, on January 20th, at 6 P.M., after the annual meeting and election, which will take place on the same date and at the same place at 3 P.M. Friends who are desirous of being present at the supper should intimate their intention to the Secretary, Mr. George J. Ingram, 50, Parliament Street, S.W.

We have pleasure in announcing that his Grace the Duke of Portland has kindly promised to preside at the sixtieth annual festival dinner of the Institution, to be held, it is hoped, in June next; but the date is not yet fixed.

RECEIVING recently my voting paper for the Gardeners' Royal Benevolent Institution, I was struck by the number of applicants (forty-four) for the pension, and that nine only can be placed on the pension list. To many it must mean years of waiting. I cannot help feeling that the Institution does not receive the support from gardeners that it deserves. I am very forcibly reminded of the wisdom of becoming a member of the Institution by looking over the names of the ten candidates who are recommended for the pension in compliance with the rules.

It was my privilege to serve under one of the candidates many years ago. Little did we then expect what was in store for the grand old place which had sheltered royalty and numbered among its visitors some of the highest in the land. Depression came, reduction took place, eventually the place was let. The old chief still held on, and now I find he is about to be placed on the pension list, and most heartily do I wish he may long enjoy it. I would urge most strongly my brethren of the craft to at once become members of the Institution, and so make some provision for the uncertain future.—ALFRED HOPKINS.

TUBEROSE CULTURE.

THE Tuberose is one of the most beautiful of all our bulbous plants, and one which should find a place in every greenhouse. The tubers are cheap in price and of most easy culture, and yet it is rarely one sees them well grown by amateurs. Many have told me that they have tried, but have always been unsuccessful. This doubtless was due to the treatment given the tubers, as with proper culture no one should fail in being successful. Failures, of course, do occur in growing Tuberose, as with everything, and in such a manner as to render it impossible to state the cause. As the present is a good time to pot the tubers, a few remarks on a method of procedure which has been found by myself, as well as many others, to be an excellent one to follow, may prove acceptable to many readers.

The bulbs should be potted firmly in 5-inch or 6-inch pots, in a compost consisting of sandy loam and leaf mould in equal parts, but any good soil will grow them quite well. One of the most important points to be considered is efficient drainage. This matter, I am inclined to think, is very often attended to in a careless manner, which cannot possibly be conducive to good health and success with this or any other plant. After having been potted they may be plunged in a frame from which frost is excluded. Let the pots remain there until it is desired to start the plants into growth, when they may be introduced into any convenient place where a slight bottom heat can be given them. They will soon commence pushing up their leaves, which always appear considerably before the flower stems. During the time they are in the frame little or no water should be given, but when they are growing freely ample supplies must be afforded, both of pure water and of liquid manure, the latter made of cow manure suiting them best.

When in flower they may be placed in a room, window, or the greenhouse, but in the event of their being used for the ornamentation of rooms it must be borne in mind that their perfume is very powerful, and that where one would scent a room delightfully half a dozen would give off a perfume which would be oppressive. This is more especially the case at night, when, like the Night-scented Stock (*Matthiola bicornis*), the scent is far more powerful than it is in the daytime.

Tuberose may also be grown with success in the garden, but the position chosen for them must be naturally warm and sheltered. In cold wet soils they are almost certain to perish. In planting out of doors, which should not be done until the weather is very much warmer, it is a good plan to take out a moderate depth of soil, substituting in place of it some thoroughly decomposed manure. Over this place the soil, the same as is advised for pot culture, in which the bulbs may be planted. Tuberose planted in the open ground in May, in the manner advised, will afford a good quantity of flowers during September.

For use in bouquets, buttonholes, and sprays the chaste white flowers are unexcelled, rivalling the Rose, Lily of the Valley, Camellia, and the fragrant Gardenia in popularity. The bulbs in potting, I have omitted to say, should not be entirely covered with the soil, but should be left with about half an inch of the apex protruding.—H. R.

SOMETHING LIKE A GRAPE.

THE berry (fig. 4, A) will tickle Mr. Iggulden's fancy, as it is very like a Tomato, and interest many readers of the *Journal of Horticulture*. I believe it is the largest Grape on record, being exactly $5\frac{1}{4}$ inches in circumference. Though what the sender, "A. S.," calls a "malformed berry," according to current acceptation of "standard" form, it was perfect, without spot or blemish, black as jet in colour, thick in flesh, juicy, and richly flavoured; finer were never seen of Black Hamburg, or, perhaps, any other Grape.

In looking for something like it I found a figure of a similar berry in Loudon's "Gardeners' Magazine" for October, 1835 (page 546), which measured $4\frac{1}{2}$ inches in circumference, and there shown in both vertical and horizontal sections. This berry was grown in a Pine stove, Vine planted outside, the grower (Mr. Thomas Forrest, Kimmel Park, Cheshire) stating that he frequently had the Black Hamburgs 4 to $4\frac{1}{2}$ lbs. per bunch, which certainly was not bad for Vines under the rafters of a Pine stove.

By giving a vertical section to the berry just alluded to it is seen to be "twin," with nine seeds, as shown in the horizontal section. "A. S.'s" is a triple (B), but only contained six perfect seeds, one ovule (a) being abortive. This horizontal section shows the arrangement of the seeds around the central axis; but still more clearly defined in the vertical section (C), the central and the side seeds corresponding to the ovaries, the berry being really a sort of three in one, thus beating the Black Hamburg berry of sixty-two years ago in Loudon's "Gardeners' Magazine."

Why some flowers have a varying number of ovaries nobody knows, but they come sometimes, and the fruit deserves tracing for the benefit of future generations—at least, such is the view of—G. ABBEY.

FIG. 4.—BERRY OF BLACK HAMBURG GRAPE.

THE AWARDED OF EQUAL PRIZES.

ONCE again the question of awarding equal prizes at horticultural shows has cropped up. Having read with interest "Sadoc's" opinion on page 597, I must confess I do not agree with him when he states that he does not think it possible for two exhibits of a similar nature to be so arranged that the merits of each are absolutely equal. I say, Point them how you like, if done impartially it is possible for the total to be the same; and if so, is it not the fairer way to place them equal? May I ask, Is it not just as fair to award equal prizes at horticultural shows, as is often done by judges in racing and all kinds of sports?

I notice "Sadoc" refers especially to the awarding of equal first prizes to a group of chrysanthemums and foliage plants at the late York Show. As I was one of the judges on that occasion, I can assure him we spent much time on the two groups in question, and every particular in which he alludes to was thoroughly considered by the six judges, some of whom were quite strangers to me; but I take it for granted they were all judges of the highest ability, or they would not have been selected for such an important show as York, probably one of the very best held in the North. It is true we were equally divided, three being for one and three for the other. At my suggestion a seventh expert was called in. He most carefully went into every detail, and he came to the conclusion that the two groups were so equal in merit that he could not conscientiously separate them. Now I contend that in such a case as this it was the bounden duty in fairness to both exhibitors to award equal prizes.—E. BECKETT, Aldenham House Gardens, Elstree, Herts.

BRIEF NOTES ON ALPINE FLOWERS.

(Continued from page 524, last vol.)

RHODODENDRON HIRSUTUM.

THE hairy "Alpine Rose" is a plant of very considerable beauty and value for the rock garden. Its hardiness is indisputable. With its companion *R. ferrugineum*, spoken of on page 524, it is one of the last of the shrubby plants to be left behind as the chains of the Alps and Apennines are ascended. In its native habitats it flowers in July and August, and presents a beautiful picture, where it grows among the rocks. Here it blooms from May to July. The flowers are scarlet or bright rose, arranged in umbellate corymbs, and with funnel-shaped corollas. The leaves are elliptical, with the edges ciliated, crenated, and marked with ferruginous dots on the under surface. It grows from 1 to 2 feet high. It has been introduced for 340 years, so ought to be more frequently seen than it is now. It grows on calcareous rocks, so that the presence of lime in the soil is not detrimental to its welfare. There is a pretty white variety known as *R. h. album*.

R. LAPPONICUM.

This Lapland Rhododendron is one of which I have no experience, and I should be glad to have some further information about it. I cannot recollect having met with it anywhere. It is described as growing 6 inches high, and as having open bell-shaped and dotted violet-purple flowers, only a few being produced in an umbel. The leaves are elliptical, half an inch long, persistent and dotted with rusty scales. I understand it is figured in the "Botanical Magazine," t. 3106. For this information I am indebted to the "Dictionary of Gardening."

R. MYRTIFOLIUM.

This is, by some, considered a variety of the well known *R. ponticum*. The leaves are smaller, being about 2 inches in length, and the plant rather dwarfer. The flowers are purple. It is not so well adapted for the rock garden of limited dimensions as a number of others, and is more suitable for the shrubbery. It is, however, mentioned for the information of those thinking of furnishing extensive and boldly constructed rockeries.

R. PRÆCOX.

This is a hybrid Rhododendron of very great beauty when in bloom. It is sometimes in full flower before the snow has gone for the season, and one is surprised that its beautiful peach-coloured flowers are hardy enough to withstand the cold weather of the time. It covers itself with flowers, which are of good size and of the most delicate beauty. Its weak point is the paucity of foliage and its partly deciduous habit. It grows from 1 to 1½ foot high, and is one which is a general favourite with all who have seen it in growth. The flowers are, in their general appearance, like those of some of the Azaleas, and many people who have not seen it before conclude that it is a member of that genus.

R. WILSONI.

This is another hybrid plant, its parentage being *R. ciliatum* and *R. glaucum*. It is to some extent intermediate between its parents in appearance, having, as has been said by a competent writer, "the foliage of the former without the hairs," and "is destitute of the glaucous hue of the latter." The flowers are rose colour. So far as the writer has been able to learn by comparison of experience, this hybrid is not quite so hardy as some of the other Rhododendrons already named, and it should therefore have a sheltered position. *R. Wilsoni* is by some said to be one of the parents of *R. præcox*.

R. DAHURICUM.

The Dahurian Rhododendron is practically a deciduous plant, and is therefore not inserted in the same position as the others. It is a good hardy species for large rock gardens, although its almost entirely deciduous habit makes it less valuable in winter. It is of erect habit, and grows about 3 feet high. *R. dahuricum* comes into flower in March, and has pretty rose blooms produced from one to three at the ends of the branches. It was introduced in 1780, and has often been figured and described.

RHODOTHAMNUS CHAMÆCISTUS.

This little shrub is also known as Rhododendron Chamæcistus, and I have, therefore, thought it better to mention it now. It is a choice little shrub, growing about 6 inches high, and with pink flowers. The leaves are what are known as elliptic-lanceolate, and are evergreen, with pointed hair at the edge. It is a remarkably difficult shrub to establish, and many plants are lost in endeavouring to induce it to grow in gardens. A mixture of loam, peat, and sand is to be preferred in which to grow it, and it may either be planted in limestone fissures of rockwork, or in beds devoted to dwarf shrubs. In the latter case, it should have its roots in contact with some calcareous matter, such as chalk or limestone.

CULTIVATION.

The Alpine Rhododendrons should be grown in soil containing a good admixture of peat. Two-thirds peat, a little loam, and the remainder sand make a suitable compost. They ought never to suffer from drought, but the opposite extreme of soil overcharged with water must be equally avoided. Some kinds require chalk or limestone, but to others it is most obnoxious. *R. hirsutum* and *Rhodothamnus Chamæcistus* belong to the former class. *R. ferrugineum* should be planted in silicious rocks. A partially shaded situation prolongs the bloom, but they do quite well in

full sun. Where planted in a position exposed to strong sunshine it is advisable to place some light material, such as cocoa-nut fibre or leaf mould, over the soil about the plants, in order that the small fibrous roots near the surface may not be destroyed. The same result may easily be attained in rock gardens by the arrangement of the stones.

As already mentioned, the Alpine Rhododendrons generally lift with a ball of earth attached, and can thus be removed at almost any time. Spring is, however, the most satisfactory season to plant them.

Rhododendrons are increased by seeds, layers, grafting, and cuttings. The ordinary grower of alpine flowers is not likely to stand in need of directions for dealing with these methods of increase, and those who wish will find full information in standard works of garden practice. It may, however, be said that there is still a field for a hybridiser who would devote his operations to the dwarfer habited Rhododendrons.—ALPINUS.

(To be continued.)

KEEPING PEARS.

IT is very evident, from what was published last week on page 621, that Pears need two forms of preservation. One is from birds and insects in the autumn, the other suitable stores to winter them in. When "W. S." referred to the trouble he had with Doyenné du Comice Pears because of the injuries done to them by insects and birds, he was but giving expression to the trouble that seems to beset everyone who grows Pears, and especially good ones. Insects and birds are no respecters of growers; but they have particular fondness for the best flavoured and sweetest fruits. That partiality, whilst it indicates good judgment, affords no palliation of their depredations.

But are good class fruits—whether on bush, pyramid, espalier, or cordon trees on or off walls—not worth some special protection? What, for instance, would be the cost of a few hundreds, or even a thousand, small cotton bags, each of about a pint capacity, made with a string run through a hem at the top, so that when the bags were slipped on the strings could be drawn tight round the stems, and thus prevent even insect access to the fruits? No doubt the fruits would suffer something in colour, or rather the lack of it; but it would be great repayment to be able to save the finest in that way. The work also from the first could be better done by the pliable fingers of women than of men, and thus the garden staff would be saved from a fresh duty. Can anyone else make any simpler suggestion? Bags of this nature washed after done with, and put away dry and clean, could be similarly utilised for two years at least.

Some precaution of this kind seems to be even more needful when Pears are scarce. Then there is the question, also slightly raised by "W. S.," and partly by the Editor, as to the best form of store in which to keep Pears, and, indeed, Apples too. Ordinary wooden or brick structures with board floors and slated or tiled roofs are of the worst for this purpose. My ideal fruit house has always been a span with walls of solid concrete 9 inches thick and 3 feet above the ground, and a thatched roof of reed or straw fully 12 inches thick; also built amidst a wood or where tall trees overhang, because there so little influenced by changes of temperature. A door of stout wood should be at each end, so that when the temperature outside was equable and cool without being frosty both doors could be occasionally opened to secure ventilation and change of air. These doors might be padded with mats and hay in very hard weather, also the eaves might be stuffed with straw or shavings if desired.

Very little of the hardest of frost would penetrate into such a house. The inner path of the house, 2 feet wide, should be 2 feet below the ground level and the floor of soil. Of course, if needed the site should be well drained. Mere trellises 18 inches apart on other side would do for shelves, as all the fruits should be as gathered laid very carefully into trays, say 3 feet long and 2 feet wide. These as filled should be placed close together on the trellises, and then if unusually hard weather set in those trays on the top trellises could be lifted down, and be laid on to the lower ones, and all be securely covered up. The temperature should range from 36° to 45°, as a very even medium. Variableness and sweating are most harmful to fruits. Whilst we have shown that we can grow the finest of fruits, our methods of keeping are open to much improvement.—A. D.

"W. S.'s, Wiltshire" remarks on Pears (page 621) are illustrative of the general need of useful information, although advice, in order to be effectual, can only be given on particular lines if no essential details are omitted by inquirers, including situation and elevation of the plantation.

One of the most adverse influences on crops is the destruction of blossoms by late spring frosts, especially affecting Pears on account of their flowering before Apples. Private gardens on low levels are likely to be sorely tried in that respect without much chance of a cure, though mitigation of the evil may not be impossible. Fruit plantations of more ambition, either private or market garden property, should be rigidly placed in favoured localities easily determined and confirmed as such. Systematic observations, if published, of the advent of irregular frosts like those in late spring would prove that the whole question turns on elevation of site, and instances in point could doubtless be adduced by some of your subscribers of the thermometer descending to a minimum overnight of say 26° Fahr. on a low level, with nearer 20° on grass, with hoar frost destroying every chance of a Pear crop, and simultaneously another Pear plantation on ground higher by 100 or 200 feet escape frost entirely with a minimum of 36°, a difference of 10°.

This example will probably be found to apply as an average one,

assuming the low site relatively in a vale with dew developing heavily and turning into white frost, and the latter on a gentle hill in the rear where, in the absence of dew, the temperature might descend to 32° or even 30°, if not lower, without leading to destruction of blossoms. Conclusions about sites on intermediate elevations can readily be drawn. Of course, shelter from the cold quarters and a gentle slope between S.E. and S.W. would be always an extra safeguard, and should be strictly adhered to, or dry cold winds might accomplish what frost failed to do. If the exercise of judgment as to selection of sites in relation to Apple and Pear and Plum plantations, with correct management, is established in this country importations will become superfluous as to bulk. It is only another case of the egg of Columbus.

A supply of lime to the stations of Pear trees has been found by observers to be productive of much benefit to fruitfulness, proving the insufficiency of that mineral in the natural soil, where its action is to render latent plant food accessible to plant action, besides absorbing superfluous humidity, and thus assisting towards the improvement of fruit and its maturity.

The classing of quality of the various Pears named in his first paragraph by your correspondent agrees absolutely with my own observations. As to Doyenné du Comice, I do not, however, find it unsatisfactory on pyramids on the Quince, and evidently the host of depredators mentioned know which Pear is the best. It produces, however, better fruit upon a wall or as an espalier. Glou Morceau ought to be satisfactory on the Quince against a wall, and also bush trained, anyhow near London. It strikes me a great omission of a first quality Pear would be made by the absence of Thompson's from any selection. I found the fruit at its best six weeks ago from a wall tree due south.

As to later sorts lasting from January to March, the best with me are Marie Benoist, Prince Napoleon, Olivier de Serres, and Doyenné d'Alençon; also the new fine French Pear Le Lectier. If more are yet wanted, Nouvelle, Fulvie, and Zéphirin Grégoire are excellent, and all are best from, and some in need of, a wall. If a situation and soil of unusual warmth be available Beurré Bosc for November and Chaumontel from Christmas are among our choicest Pears.—H. H. R., *Forest Hill*.

THE YOUNG GARDENERS' DOMAIN.

ONIONS FOR EXHIBITION.

I HAVE found the best method of growing Onions for exhibition purposes in the northern counties is the following:—About the first week in January sow the seeds thinly in an ordinary seed pan, well drained and filled to within half an inch of the top with finely sifted soil. Place the pan in a slight bottom heat until the plants are about 1½ inch high, then prick out into boxes (or better still a slightly heated pit or frame) 3 inches apart. The soil should consist of two parts of loam, one part of leaf mould, and one part of old Mushroom bed refuse, with a liberal addition of wood ashes, or, failing those, finely sifted ashes from the stokehole fires. Here they must remain, gradually hardening until the first or second week in May.

Prior to this have the ground prepared for their reception in the following manner. Give a good coating of half-decayed manure, and dig well in. If the soil is of a clayey nature ashes applied when digging will be of great benefit. If Parsley can be sown on the ground the first week in February it will act as a deterrent against the Onion fly. This having been done, and the ground made fairly firm, choose if possible a dull, moist day in the first or second week in May for planting. Lift with a good ball of soil and plant firmly in rows a foot apart and 10 inches from plant to plant, and keep moist until well started. During the growing season applications of liquid manure occasionally are of great benefit, and as there is such a variety of excellent artificial as well as animal manures, it is advisable not to use the same stimulant twice in succession. Also keep the soil well stirred amongst the plants. The varieties I have found best for exhibition are Ailsa Craig, Banbury Improved, and Excelsior.—J. C., *Lancashire*.

EARLY FORCING PEACHES AND NECTARINES.

EITHER December or early in January is the usual time for starting first early houses of these highly appreciated fruits. After the houses and trees have been thoroughly cleansed, the pruning having been previously done, we commence the training of the trees. This must be carried out systematically, leaving sufficient room between each shoot for the summer's growth to be tied in without overcrowding. A start may be made with a temperature of 40° to 45°. If the roots are near the surface it may be advisable to apply a top-dressing, and I have observed that a sprinkling of lime and about 2 or 3 inches of loam, with which has been previously mixed a small quantity of mortar rubbish, have been followed by markedly good results. Should the trees be in a weakly state, add a few half-inch bones and wood ashes. Make as firm as possible, and give the borders a thorough watering. Syringe the trees freely in favourable weather and pay the greatest care to ventilation, being governed in this by the state of the external air. In my opinion it is advisable to allow the temperature to increase a little rather than admit a cold draught, which is almost sure to give a check to early forced trees. Commence with the top ventilation in the early morning, and increase it with the temperature, and close before the sun leaves the houses in the afternoon. In about a fortnight or three weeks increase the temperature a few degrees until 50° by night is reached, which I think sufficient for the flowering stage. Should the flower buds be too numerous, it is advisable to thin them, leaving the strongest and best.

During the flowering season a drier atmosphere must be maintained, and it is frequently advisable to assist the distribution of the pollen about midday by one of the several efficient methods. A constant circulation of air is essential when the plants are in flower. As soon as the petals fall a gentle syringing with tepid water will greatly assist the embryo fruit to swell. Disbudding must be done at intervals of a few days, as there will then be less danger in giving the trees a check. First rub off with finger or thumb all "breast shoots," then commence at the leader of each branch, leaving the first shoot, and remove about half of the weakest growths except the two at the base. At the final disbudding leave only the leader and one at the base of each growth bearing fruit. If that be rather long one intermediate growth may also remain. Tie each growth as soon as long enough.

As the fruit commences to swell raise the temperature gradually to 60°, and later on 65° by night, with 5° to 10° higher in the day. Thin the fruit freely, taking the state of the trees into consideration. An occasional top-dressing of artificial manure may be given before watering if the trees require it, while liquid manure is also beneficial to them if they are too weak to support the fruit. Keep a sharp look out for green fly and red spider, which must be promptly exterminated either by syringing or fumigation, or the pests will quickly ruin the young growths, and so spoil the next season's crop of fruit. The trees must never be allowed to suffer for want of water, or bud dropping will be the result. At the same time the border should never be sodden, or injury to the roots will quickly follow. As the fruit commences to colour it must be exposed to the sun, which is essential to obtain the best flavour, and as it begins to show signs of ripening admit air more freely day and night. When the fruit has been gathered the next thing is to ripen the wood thoroughly by leaving open all the ventilators both day and night, and water the borders as often as required until they lose all their foliage.—J. F. D., *Yorks*.

FRUIT FORCING.

Cherry House.—The trees in the house started in December are fairly on the move, and the day temperature must be kept at 50° to 55°. If the days are bright air should be admitted, but only to the extent of keeping the temperature from rising above 65°, maintaining it from sun heat at 60° to 65°, admitting a little air at 50°, more at 55°, above which a free circulation of air must be allowed, and when the temperature declines to 55° close the house for the day. The night temperature should still be kept at 40° to 45° artificially. Syringe the trees in the morning and early afternoon if the weather is bright, but if the weather be dull it will suffice if the borders and other surfaces are damped whenever they become dry. Examine the borders, supply water if necessary, moistening them thoroughly, the water not being less or much higher in temperature than that of the house. Trees in pots—the most desirable mode of forcing Cherries—must be well supplied with water, repeating the supplies as necessary to insure thorough moisture in the soil.

Cucumbers.—Take care to husband the sun heat, giving a little ventilation if the weather be mild and calm in the early part of the day, and close early in the afternoon, or shortly after midday, damping the house at the same time. Sprinkle the floors on fine mornings, and syringe the plants lightly, thus discountenancing red spider, and to some extent holding the pest in check. Supply weak liquid manure to plants in free growth, and to those not showing signs of growing freely sprinkle a little superphosphate and soot on the soil, and use tepid water only until the growth becomes free. To encourage surface roots a top-dressing should be given of turfy loam from the size of a nut to an egg, intermixed with a fourth of sweetened horse droppings, having it previously warmed to the temperature of the house, and sprinkle on this a handful of some approved fertiliser. Maintain the night temperature at 65°, a few degrees less in severe weather and a few more in mild, 70° to 75° by day, and 85° to 90° with sun heat, keeping the bottom heat steady between 80° minimum and 90° maximum.

Where winter Cucumbers are not grown plants for the early supply of fruit should now be prepared, sowing the seeds singly in 3-inch pots half-filled with soil, so as to leave space for top-dressing when required. Plunge the pots in a brisk bottom heat near the glass, or place on shelves and cover with a pane of glass, removing as soon as the seedlings are just clear of the soil. These plants will be available in about a month for planting in houses, pits, or frames, and will supply fruit during the month of April. Where convenience for raising the plants for planting in frames does not exist seed should be sown in pots placed in a hotbed as advised under Melons.

Melons.—To have ripe fruit late in April or early in May seeds must now be sown singly in 3-inch pots, leaving room in the pots for top-dressing. Plunge in a bottom heat of 80° to 90° near the glass, or cover the pots with bits of glass and remove when the plants appear; thus plants can be raised on shelves in any structure having a temperature of 65° to 75° by artificial means. As soon as the plants have unfolded the first leaves top-dress the soil, keep them as near the glass as possible without touching so as to prevent a weakly growth.

Hotbeds.—In small or moderate-sized establishments, where there are no light well-heated structures for raising Cucumber and Melon plants or others from seeds and for rooting cuttings, a hotbed is very important. The materials may consist two parts of leaves and one part of stable litter, well mixed and thrown into a heap, damping if necessary, and turning over twice, the first time when the materials are warmed through, and again in the course of a week. This sweetens the material, rendering it fit for making up. Choose a dry site and in front of a wall or hedge to the north, and if similar but low on the east-west the force of winds will be much modified. Make the bed 6 inches larger than the frame every way, but as it is difficult to carry up the sides and ends quite perpendicular, let the base be 1 foot greater than the box every way, building the bed so that it will have about 6 inches to spare all round the frame. Put the materials together as evenly as practicable, and beat them down as the work proceeds, making the bed about one-third higher than the intended height, the bed at this season needing to be about 6 feet high at the back and 5 feet in the front.

In a week the bed will have settled down, then level the surface, return the frame, and put in sufficient fermenting material to make the back of the frame correspond in depth with the front, and over this 4 to 6 inches of leaves or other light material for plunging the pots in, whether of seeds or cuttings. We find it an excellent practice to form a cavity inside the frame, in order to allow the plants the benefit of top heat from linings after that from the bed is declining. Due preparation must be made of fermenting material for linings and hotbeds for the plants as they become fit for planting in the fruiting beds.

Pines.—When it is found that plants under the ordinary régime will not fruit sufficiently early for particular purpose, a selection must be made from the successional plants, choosing those which appear likely to show fruit quickly, these being readily distinguished by the high centres or hearts and stoutness at the upper part of the plant stem, and bringing them together into a light house, where they can have the benefit of more heat. Plunge the pots in a bed standing regularly at a temperature of 90° to 95° at the base of the pots. If the plants are in the least dry, water them with liquid manure copiously at the same temperature as the bed. Maintain the top heat at 65° to 70° at night, with 5° more from fire heat by day, advancing to 85° or 90° from sun heat. Keep the atmosphere about the plants in a genial and invigorating condition by damping the paths and sides of the beds as they become dry, and lightly syringing as may be necessary.

Peaches and Nectarines.—*Earliest Forced House.*—The trees started in December will require a night temperature of 50° to 55°, the latter only when the nights are mild, and as a maximum by day when the sky is overcast, 65° by day from sun heat, and if the air be mild a few more degrees may be allowed. Cease syringing the trees directly the anthers show clear of the corollas, but damp the floor and border on bright days in the morning and afternoon. Lose no opportunity of ventilating freely when external conditions are favourable, and when the pollen is sufficiently advanced choose the warmest and driest part of the day for aiding its distribution by shaking the trellis or tree, or taking a camel's-hair brush, applying the pollen to the stigmas. If there be a deficiency of pollen of any variety, some should be taken from those that afford it freely and applied to the pistils; a rabbit's tail tied to a small stick holds the pollen well, and allows the cross-fertilisation to be readily effected. Inside borders must not be neglected for water; protect outside ones with leaves and litter, just sufficient covering to exclude frost, but not so thick as to perceptibly ferment.

Second Early House.—This, the first in most establishments, and planted with such varieties as Alexander and Early Louise Peaches and Cardinal and Advance Nectarines, must be started to give fruit early in May; or if such varieties as Hale's Early, Dr. Hogg, Stirling Castle, Royal George, Grosse Mignonne, or Dymond Peaches; Early Rivers, Lord Napier, Stanwick Elruge, and Rivers' Orange or Humboldt Nectarines, to give ripe fruit at the end of May forward, must be started at once. Damp the trees in the morning and early afternoon, turning on the heat in the morning, so as to raise and maintain through the day a temperature of 50°, taking care that it does not exceed that heat by artificial means, allowing the temperature to rise to 65° with sun heat, and free ventilation from 50°. When the buds swell maintain a night temperature of 40° to 45°, up to then merely excluding frost.

THE KITCHEN GARDEN.

Forcing Kidney Beans.—Little progress is made by Kidney Beans during the dull, cold days of midwinter; but if forcing is commenced now, a remunerative and much appreciated crop should result. These early plants succeed best in 8-inch and 9-inch pots. Fill well-drained pots to within 2 inches of the rim with moderately rich loamy soil, making this firm; sow nine or ten seeds in each, and cover with soil. If no other bottom heat is available, arrange the pots on the hot-water pipes, this causing the seed to germinate quickly and strongly. Before the plants become drawn and spindly, raise them well up to the light, in a brisk heat of 65° by night to 70° and 75° in the daytime. Thin out to not more than six plants in a pot, and lightly support with Birch spray or stakes and raffia; keep the roots well supplied with water and liquid manure, and syringe freely soon after midday when the weather is clear.

Cauliflower.—If there is an insufficiency of plants of early and second early varieties saved from the autumn sowing, the requisite number should be raised now. It is also advisable to be prepared for the possible loss of late Broccoli plants. Sturdy plants of Dwarf Forcing or Early Snowball, established in small pots and duly turned out into a rich bed of soil in a pit or frame, would produce neat little hearts well ahead of

plants in the open, or in time to obviate any difficulty that might accrue owing to loss of late Broccoli. Sow the seeds thinly in pans, and place in gentle heat to germinate. Raise the seedlings well up to the glass to keep them sturdy, taking care not to break them down by reckless syringing. When well into rough leaf transfer to a warm greenhouse shelf, a fortnight or three weeks later potting them singly into 3-inch pots.

Lettuce.—The mild autumn and early winter months have had the effect of stimulating a stronger and later growth of plants than desirable, so that there is every likelihood of small plants being scarce this spring. The way out of this difficulty is to sow seeds of such quick hearting sorts as Early Paris Market, Golden Queen, and Commodore Nutt now thinly in pans or boxes, and otherwise treating as advised in the case of early Cauliflower. A portion of the plants may, when strong enough, be pricked out in a shallow frame or pot on a bed of soil over a mild hotbed, where, if properly attended to, they will heart in early, paying well for gentle forcing. The rest can be hardened and duly planted at the foot of sunny walls or on warm borders.

Mustard and Cress.—A regular supply of this quickly grown, popular, small salading ought where possible to be forthcoming now. It is well to sow it in separate boxes, Mustard frequently growing and ageing the more rapidly. Fresh rich soil ought always to be used. Make the surface of soil firm, moisten prior to sowing the seed thickly on the surface, press it in evenly, and scarcely cover the Mustard only with fine soil. If placed in a moist atmosphere and brisk heat, and further heavily shaded, not removing the covering till the salading is 1½ inch high, it will be possible to cut it with long, clean, well blanched stems. The less watering needed for the first week the better. Transfer to cooler quarters to keep it tender as long as possible, and sow more seed every week.

Tomatoes.—In the event of no plants having been raised in the autumn, and early crops are desired, seeds should be sown at once, giving the preference to known free-setting early ripening varieties. Sow the seeds thinly in pans of light soil, and place in a brisk heat to germinate. Soon after the seedlings are up raise the pans to near the glass, keeping them there till they have formed a second pair of leaves other than their seed leaves. Thus treated a number of sturdy plants will soon be ready for placing singly in small pots. Being well apart they can be lifted out of the pans with the point of a label, all having a little soil about the roots, and not receiving any noticeable check; whereas others thickly raised, and which have to be shaken clear of each other, are slow in recovering from the move. If kept somewhat closer and warmer for a few days to hasten root action, the plants should be returned to a sunnier lighter position in time to keep them sturdy. Tomato plants ought to be placed in their fruiting quarters before they become root-bound and stunted in growth.

Exhausted Mushroom Beds.—Mushroom beds in heated structures that have produced a crop will frequently do good service a second time if properly treated. No old stumps ought to have been left in to decay and spread a destructive fungoid growth all round, but all should be twisted out with the Mushrooms. In the case of large clumps, if these are removed bodily a large hole is formed, which must be filled with fresh loam. If the beds have been on the dry side a thorough soaking with either clear liquid manure, or, better still, water well impregnated with salt (¾-oz. to the gallon of water), in a milkwarm state in either case, may lead to a capital second crop.

PLANT HOUSES.

The Conservatory.—However well plants may be grown or effectively arranged this structure cannot be thoroughly enjoyed unless the surroundings are perfectly clean, therefore the stages, glass, and woodwork should be washed occasionally. The house is now gay with dwarf Poinsettias, Euphorbias, Centropogon Lucyanus, Primulas, Cyclamens, Cinerarias, Heaths, Solanums, Rhododendrons, and many bulbs.

Epacris.—These may be brought forward into bloom by introducing them into gentle heat. Their slender stems crowded with flowers are charming when arranged to stand above plants of a dwarf compact habit. At no season are these plants more highly appreciated or display their beauty to greater advantage than during this and the following month. Their flowers last much longer now than when the sun has gained considerable power. This is not the only advantage, for the plants start again much earlier into growth, and therefore have a long season before them, and every chance of the growths being thoroughly ripened, without which the plants cannot be expected to flower profusely.

Tulips.—The early Tulips that were placed thickly together in pans and boxes, and are now being forced, should, as they show the colour of their flowers, be lifted out. By so doing even pots or pans can be made up, and the flowers will last equally as long as if they were established. Early in the season it is difficult to have even pots of bloom unless this course is followed, for the bulbs flower very irregularly. Keep them well watered after they are placed in pots. Single crowns of Lily of the Valley can be treated in the same way, and then full pots of flowering spikes are certain. The last, if forced in strong heat, must be gradually hardened before being cut or taken into rooms or the conservatory, and it will be found that they will last nearly twice the length of time that would be the case if cut direct or taken into rooms from a close, warm house or frame.

Fuchsias.—Young plants rooted towards the end of August, and kept in small pots, may now be placed in 5-inch pots in a compost of loam, one-third leaf mould, one-seventh decayed manure and sand. Arrange

the plants near the glass, and maintain a temperature of 50° to 55°. Ventilate on favourable occasions after the young plants are established and have commenced growth. Old plants that have started into growth may have the roots reduced to at least one-third, and be repotted in the compost advised above. The plants can be placed in pots one size less until they are in active growth, when they can be transferred to their largest size. If careful watering can be insured until the plants are established they may be potted at once in a large size.

Cannas.—These are very useful in 5 and 6-inch pots for association in groups in the dwelling house or conservatory. Clumps that have rested under the stage of a cool house for some time may be started in the gentle warmth of a vinery or Peach house. Directly they commence growth divide them and pot singly, for they can be used to greater advantage in most arrangements than when a number of shoots are allowed to grow together. These plants will do well in any moderately rich soil.

Solanums.—Where cuttings were rooted in August and have been kept in store pots they may be placed singly in 2-inch pots; if they have been kept in thumbs they can now be transferred to 3-inch pots. Good plants well set with berries can be produced from cuttings struck early in the season, but better result from autumn striking. When autumn plants have not been provided cuttings should be rooted as early as possible and pushed forward in gentle warmth until the plants are ready for their final shift. Encourage young plants to grow after potting by keeping them in a temperature of 50° to 55°. Pinch the shoots at times to induce a branching habit. Use for a compost fibry loam, one-seventh of manure and sand.

Lantanas.—Place young plants now in 2 and 3-inch pots into 5-inch pots, and grow them in the compost advised for Solanums, and under the same treatment as Fuchsias.

Bouvardias.—Cut back plants that have been rested since they flowered, and introduce them into a temperature of 55° to 60°. Under these conditions they will soon commence growth and yield good cuttings. Those who favour raising the plants by portions of the roots may now cut up the roots of well rested plants into lengths of about half an inch. Place two or three of these in the centre of 2-inch pots filled with light sandy soil; the portions of roots should be covered with a quarter of an inch of fine soil. Place the pots in brisk heat, and be careful the soil does not become dry. If slight bottom heat can be given them all the better. Keep plants that have recently flowered rather dry at their roots for a time.

PROGRESS OF BEE-KEEPING.

WITH the advent of the new year it may be an advantage to compare the present with the past, and endeavour to find out, as far as it is possible, what advance has been made of late years in bee-keeping. That progress has to be chronicled there can be little doubt, although some districts have signally failed to make the headway that might have been expected. There have been various causes for this, the chief one being foul brood. This disease has devastated numerous colonies of bees in the South and West of England. It has been found the worst in outlying districts where bees have been kept from time immemorial in straw skeps.

It may be as well to remind bee-keepers that in all probability stocks that were affected with this disease in the autumn will have succumbed; and when this is the case, and they are in straw skeps, it will save further mischief if they are committed to the flames.

From other districts, and it is gratifying to know they are in the majority, great strides have been made during the past ten years. In every instance that has come under my notice it has been where the modern system, or moveable frame hives, has been worked for storing a surplus. If straw skeps have been in use it has been for supplying early swarms, and when worked in conjunction with frame hives they are a decided advantage.

Gardeners have not been slow to observe the benefits derived from bee-keeping, even when honey production is of secondary consideration, owing to the amount of good bees do in the fertilisation of the bloom. During the past ten years a great advance has been made in this branch alone, and it is now quite unusual to visit a garden in the provinces and not find a hive or two of bees.

In favourable districts throughout the country large apiaries have sprung up during recent years, and many tons of honey are obtained where little was previously procured. In some instances men devote the whole of their time to the industry of bee-keeping and the supplying of bee-keepers' requisites.

SAMPLE OF HONEY OBTAINED.

One of the most remarkable things in connection with bee-keeping of the present day is the superior quality and sample of honey obtained under the modern system. If one will look back and compare the

honey that was brought into our provincial markets not more than twenty years ago with what one may see to-day, any ordinary observer will be at once convinced of the great strides that have been made. At that time, and in fact several years later, honey was brought into the towns by country people and offered for sale in a variety of utensils. The major portion was of inferior quality, owing to the large amount of bee bread that had become incorporated with it; this was most apparent when it was obtained from the brood combs, which it invariably was.

Now all this is altered; run honey is tastefully put up in glass jars specially made for the purpose, in sizes to suit customers, many bee-keepers labelling their own produce, which in the end may prove an advantage to them in finding other customers. It is also a mark of genuineness. The honey, too, when obtained from various sources is not mixed, so that a bee-keeper may with a little practice be able to say whether a given sample of honey has been obtained from field Beans, White Clover, Limes, or other source.

It was impossible to distinguish the various samples of honey with any degree of certainty under the old system; consequently, good, bad, and indifferent were mixed.

FINDING A MARKET.

Some bee-keepers experience a difficulty in finding a market for their produce, and it is certainly discouraging after a good honey harvest to be unable to secure an outlet on favourable terms for the surplus one may have. Personally, I have no difficulty in this respect, as taking one season with another we get our share of honey, which is often ordered before it is obtained, and it is several years since any remained unsold after this date.

From numerous letters to hand others, although obtaining it in much less quantity, are unable to find a market. In some instances, this is owing to demanding too high a price; in others, for want of care in making a good sample when preparing run honey. It is advisable to keep each crop separate, which is easily done when extracting. If a sample of each is placed in a glass jar and labelled the bulk may then be stored until required for bottling or any other purpose. A comparison of the various samples can then be made at any time, and is a much more satisfactory plan than mixing.

Bee-keepers should endeavour to create a local demand. If honey can be disposed of in the neighbourhood it is a saving of labour and expense. It is surprising what may be done in this respect. The bee-keeper's aim must be to always supply a good article. If run honey is dark and not of good quality, it is much better to feed it back to the bees than to lose a customer, and always to send a sample from bulk, as there will then be no complaint. Comb honey requires care in manipulation; this is usually obtained in 1 lb. sections, and it is not often that the bee-keeper can get them all first-class.

The difficulty usually experienced is to get the bees to finish them off without leaving any empty cells, or some partly filled. This is the case when a spell of cold weather sets in, or when honey is scarce. It is therefore advisable to have two or more samples. The returns will then be made more satisfactory. There is not such a demand for honey in the comb as for run honey.—AN ENGLISH BEE-KEEPER.

A REMINDER FOR "GEORGE HOWDENSHERE."

It will be remembered that some months ago a discussion appeared in these pages between "An English Bee-keeper" and "George Howdeshire" on the relative merits of a hive with ten standard frames and those of larger dimensions. "George Howdeshire" promised the readers of this Journal that after a trial with nearly one hundred large and small hives in the locality where he resides, he would make the result known to the readers of this paper. It would be interesting to know if any of the large hives have come up to the 350 lbs. mentioned in this Journal some time ago.—A YORKSHIREMAN.

* All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8. Rose Hill Road, Wandsworth, S.W.**, and **NOT** to Mitre Court Chambers. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Abnormal Growth on Thorn Hedge (W. G.).—The growths are infested, or rather have been, with the Thorn leaf-rolling mite (*Phytoptus crataegi*), which, in some cases, seriously interferes with the growth for several seasons together, and then entirely takes its departure. There does not appear to be anything beyond that on the sprays, but they were withered when received, and only showed traces of the leaf margin thickening and inrolling. Late attacks sometimes cause flower buds to start into growth at the dreary period, but such occurrences are very rare.

Stoneless Grapes (Young Grower).—Such splendid clusters would be highly creditable to an old grower if all the berries were the same size as one of them—namely, $4\frac{1}{4}$ inches in diameter and nearly round, or much rounder than those of Black Alicante usually are. This huge berry only contained three seeds, the majority, about half the size, containing, some two seeds, and others only one seed, while the too numerous smaller berries are seedless. As the border contains "plenty of lime rubbish," and has received in addition an annual dressing of lime, you do not think the lack of seeds is attributable to absence of lime; all the same, we should not hesitate to apply 4 ozs. of basic slag and 2 ozs. of sulphate of potash per square yard now, pointing lightly in. We attribute, however, the condition of the Grapes mainly to defective fertilisation. It may be that the stigmas were excessively moist at the time of pollen distribution, which we have known to occur in the case of this usually free setting variety, and especially with vigorous Vines. Pay attention to atmospheric conditions another year during the flowering period, and satisfy yourself that there is a free distribution of the pollen to not over-moist stigmas, and we think you will secure a more uniform set and better standard fruit.

Brown Scale (H. G.).—This pest, of which there are several species, does not live apart from the living trees or plants. If you brush off the scale while soft it cannot live, like mealy bug, in the soil or about the houses, for when once fixed it is so for life, not having power of locomotion, the legs being dispensed with at a comparatively early age as parts no longer useful. But if you leave the scale until mature, quite hard and brown, the small dust-like eggs fly in all directions, as you have no doubt observed, and these—the only hibernating form of the insect—may live over the winter, and then, hatching out, the larvæ ascend the trees or plants and fix themselves after a few days by their beaks into the tissues for the purpose of drawing nourishment. When first hatched they are whitish woodlouse-like creatures, and are then very easily killed by the usual advertised insecticides, fumigation with tobacco, or vaporisation with nicotine. You are not bothering us in the least about these pests; we are pleased to render any service to our subscribers. You are quite right about the insects being difficult to kill on young wood, such as that of Peach trees, as during the winter the pests are in the egg state and often not reached beneath the scale, or this falls with eggs intact, and the young appear in the following spring. Petroleum emulsion, however, kills all with which it comes into contact, and even better is caustic soda and potash solution, but this requires to be used carefully on green shoots of Peach trees, and in every case the solution must reach the eggs. In stoves and similar structures the pests breed the year round, and the cleaning being often deferred until the scale becomes hard the eggs are scattered far and wide. Frequent fumigation is unquestionably the proper thing, as when just hatched the larvæ are as easy to kill as green fly, and soft scale cannot possibly return to the plant when once removed. The eggs, therefore, are the source of infestation, and often carried from house to house on the clothes of workmen, and in other ways.

Lawn Manure (H. C.).—The formula is good, but whether the best for your purpose no one can know in the absence of information on the character of the soil, the present condition of the sward, and as to whether an increase of Grasses or Clover is most desired. For present or early application you would not err by using thrice the amount of superphosphate, reserving the nitrate of soda and salt for a dressing in March.

Aquatic Plants (A. Johnson).—For pond margins *Menyanthes trifoliata*, *Rumex hydrolapathum*, *Typha angustifolia*, *Carex pendula*, *Scirpus lacustris*, *Butomus umbellatus*, *Calla palustris*, *Lysimachia thyrsiflora*, *Acorus gramineus*, *Iris pseudacorus*, and *Lythrum roseum superbum*. These all grow well on or close to the edge. To plant in the pond bottom there are *Nymphaea alba*, *Nuphar lutea*, *N. advena*, *Villarsia nymphaeoides*, *Stratiotes aloides*, *Pontederia cordata*, *Aponogeton distachyon*, and *Hottonia palustris*.

Planting Anemones (C. J.).—Choose the first fine day when the soil works cleanly for planting your Anemones. They are best planted in the autumn, but will do now. Draw drills across the bed 2 inches deep and 5 or 6 inches apart, and plant the tubers 5 inches apart in the rows. For choice varieties a thin layer of sand scattered under and around each tuber will be useful. As soon as the bed is planted cover the tubers with sandy loam from a basket or wheelbarrow. Take care that the tubers are placed the right side up, by observing the side that has the old small fibres on it. That side place next to the bottom of the drill. When all are planted and covered up the right depth (2 inches) level the surface with a garden rake.

Eucharises Losing Their Leaves (Puzzled).—The plants have evidently received a check by some cause or other. This would occur if they were removed to a cooler position than that which they previously occupied. You say the pots are not embedded in tan or anything else. If they were plunged prior to their removal the roots would probably receive a check and the leaves fail. If you can now plunge them in a warmer position in the house they will be safer than with the pots exposed, inasmuch as the root moisture will be more uniform, and this must by no means be excessive during the present month, all that is necessary being to keep the soil perceptibly moist. If you can keep the roots healthy and the bulbs are large enough, flowers may be expected in due course. You do not say if the plants have flowered previously.

Ramondia pyrenaica (B. T. J.).—The plant you name inhabits a somewhat varied area in the Pyrenean and Piedmontese Alps, oftentimes on the steep and almost perpendicular faces of the rocks. When so situated, however, it is generally where moisture is in abundance, as it is impatient of drought, preferring protection from hot sun. This, however, is of not so great moment as a plentiful supply of moisture in a well-drained position. Plant it in equal parts of peat and loam, together with a liberal addition of silver sand or grit—it delights to send its tiny fibres into moist sand—and success will invariably attend the operation. From its extremely prostrate habit of growth it is not to be recommended as a border plant, since heavy rains keep the plant almost wholly covered with earth; but on a mound above the ordinary level it may be made as equally at home as in its native habitat. It is chiefly increased from seed, though now and then some few plants throw out offsets; but to detach these with roots is a very dangerous operation, and should always be avoided. Sow the seed as soon as ripe. This will be about the middle of August, and the seedlings will appear the following spring. Do not be discouraged by the slow growth of the seedlings, which is remarkable. When the seedlings are of sufficient size they may either be potted or pricked out in small colonies on the rockery.

Growing Endive (Amateur).—It is hardly worth while sowing Endive before the middle of June for the first main crop, the principal crop—that is, for winter use, needing to be sown early in July, and that for spring use at the end of that month. The seed may be sown in drills 15 inches apart and the plants thinned to 1 foot distance in the rows. This is the best for the early crops or those that have to be blanched on the ground, for which there is no better method than tying the head with matting or covering them with pots, closing the apertures so as to exclude light. The leaves should be gathered together and tied near the top, and in a week afterwards they should be again tied, this time about the middle, and the plants must be perfectly dry. About ten days in summer and three weeks in winter are necessary for blanching. The crops that are intended for lifting and placing in frames are best sown thinly in rich fine soil in shallow drills about 4 inches apart, sowing the seeds thinly, thinning to 3 inches apart, and when having four leaves take up carefully and plant in rows 15 inches apart and 1 foot asunder in the rows, watering as required. These lift with better roots than if not transplanted. The plants should be placed in frames or pits before being frosted, be well ventilated in favourable weather, and protected in severe weather so as to exclude frost. Blanching is effected in the same way as with those outdoors—namely, by tying up the leaves about three weeks before the heads are required for use, tying up a quantity each week, by doing which a constant succession of blanched heads will be secured. Late crops may be planted at the foot of walls or in frames protected from frost, and are blanched in spring same as the early crops by tying, covering with pots, or placing a slate or tile over the curled varieties.

Names of Fruits. — Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow

themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (H. K.).—1, Nec plus Meuris; 2, Easter Beurré; 3, Winter Nelis. (T. H. B.).—1, Alfriston; 2, Northern Greening; 3, New Hawthornden; 4, Newton Wonder. (Amateur).—Excellent examples of Cox's Orange Pippin. (P. B. S.).—1, Gloria Mundi; 2, Golden Winter Pearmain; 3, Ribston Pippin; 4, Blenheim Pippin. (C. F. H.).—Passe Colmar.

Names of Plants.—We only undertake to name *species* of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (P. P.).—1, A variety of *Cypripedium insigne*; 2, *Lælia anceps*; 3, *Cypripedium barbatum*. (F. T.).—1, *Ophiopogon jaburan variegatum*; 2, *Bambusa Fortunei*; 3, *Kentia Canterburyana*; 4, *Dieffenbachia picta*; 5, a variety of *Coleus* that could only be named by comparison in a large collection. (A. W. W.).—1, *Tillandsia Lindenii*; 2, *Phoenix dactylifera* (the Date Palm); 3, *Selaginella Kraussiana*. (L. S.).—1, *Meyenia erecta*; 2, *Oncidium tigrinum*; 3, dead.

A PROFITABLE OUTING.

MR. BARLOW sends his two pupils out for a walk together in the country lanes; one returns, having met with nothing whatever of interest; the other, on the contrary, can discourse fluently for hours on the beauties and curiosities he has seen. He is a bit of a prig, but, after all, is much more to be admired than the boy who just strolls along with dull eye and inactive brain. How many of us are like Sandford and Merton, the two pupils of Mr. Barlow? We fear we often miss many and great opportunities for self-improvement through idleness, or perhaps ignorance.

Then, again, we frequently see things that interest us greatly, but having no command of language or powers of description, we cannot impart our information to others, and we do not trouble to cultivate the gift of narration. *En passant*, we may remark that this branch of a child's education is often neglected, and surely there is nothing much more pleasing than a pithy speech, or a neat, well-constructed, essay.

An extract from the "Surrey Mirror" "On Agriculture on the Continent" has come under our notice, and we are greatly pleased with the manner in which the subject is treated by the writer, Mr. A. Holm, jun., of Belchworth—a student who achieved great distinction at the South-Eastern Agricultural College (County Councils of Kent and Surrey) at Wye—winning, in addition to the gold medal of the Royal Agricultural Society of England and other honours, the scholarship offered by the Surrey C.C. to investigate agriculture in Denmark and Sweden. We highly commend the wisdom of a step like this. A young man specially well educated in agriculture is allowed the chance of travelling in company with some of the leading agriculturists of the day, and sees under the most favourable aspects the farming methods of Denmark and Sweden.

We treated of this dairy tour a few months ago, but the information worked on then was by no means so full as these notes now before us. Personal friends told us much of interest, but they did not see things with young, fresh eyes, nor did they make their narrative so interesting.

The first great event of the tour was the inspection of Wedellsborg, on the Island of Jutland, the estate of Count Wedell. The property extends over 54 square miles, and the home farm is of large extent—namely, 940 acres. It appears all is under the plough save 110 acres, so that the labour bill must be heavy. The cattle are entirely of the Red Danish milking breed—190 milk cows, and 110 young stock. In this herd the tuberculin test is used twice a year. These good people are more awake than we to the dangers and losses arising from tuberculosis (English farmers, please copy). The

pigs are a cross of Yorkshire and the Danish breed. Mr. Holm evidently has an eye for a horse, for here he sees room for improvement. We do enjoy seeing a good even stud of draught horses. Fancy a barn to contain 2000 tons of forage!

From Wedellsborg to Copenhagen, and the first object of interest to see was the Milk Supply Company. The milk of 5024 cows is here dealt with, and the hands employed number 300. On arrival the milk is sampled, strained through gravel and fine cloth, bottled and pasteurised, and sold for infants at 1s. 3d. per gallon. Of course the diet of the cows is strictly regulated.

An interesting paper was read by Herr Bernard Boggild on "What the Government has Done to Develop the Dairy Industry in Denmark." A yearly grant of £5500 is made to the Laboratory for Agricultural Research, and a similar sum is spent on stamping out tuberculosis in cattle. Here is an example for our Government; the pest will not be checked here till similar measures are taken. There are also other grants for matters of minor moment, and skilled experts are at the call of those dairy farmers who need their advice free of all cost save travelling expenses.

The colleges connected with agriculture were next visited. The State butter show, and on the following day the agricultural and experimental station at Lynby. The school is one of several, the result of private enterprise, that have been founded during the last thirty years. These schools instruct about 3000 young men every winter, and in the summer the same number of young women, drawn principally from the working classes. These schools seem to get hold of the right material to work on, and how creditable it is to the population to find them ready to embrace these opportunities.

We must not linger in this pleasant Danish land, but away with Mr. Holm to the Co-operative Dairy at Lund in Sweden, where 6000 gallons of milk are daily manipulated, the farmers receiving their separated milk back again. Then there was the college and dairy school at Alnarh. Government grants to this enterprise £2080 per annum, and the college is divided into the following departments:—

- I.—A Higher Agricultural College.
- II.—Lower ditto.
- III.—Higher Dairy College.
- IV.—Lower ditto for men.
- V.—Lower ditto for women.
- VI.—A Horticultural College.
- VII.—A Farriery School.

As far as we can gather instruction and board in the lower school are free, thus admitting a class which otherwise would stand little or no chance of technical education. Of course, the higher grade students pay, but the terms are by no means extravagant.

About the Stockholm Dairy Company we note one point: the managers do not pasteurise their milk intended for infants, but instead have an elaborate system of filtration. Our knowledge of the requirements of infants is not very great; but we do know that for some children the boiled—i.e., pasteurised—milk would be most unwholesome. It is not natural, and therefore should only be used as a *dernière resoit*—that is, if no really safe milk can be obtained.

On the estate of Hamra, belonging to the Alpha-Laval Separator Company, are conducted experiments in dairying and cattle-breeding, and the favourite type of cow is red-and-white, a cross of Ayrshire and Shorthorn, first-rate milkers.

There is a college farm at Uttana of 1400 acres; plenty of scope here for the pupils. Here, again, we find an upper and lower school, the latter within the means of youths wishing to become bailiffs.

Mr. Holm sums up by saying the Dane and Swede work harder and make longer days than our men like; and he adds that he thinks abroad greater attention is paid to the feeding of stock than in England. We think this must apply to small owners only, as on large, well-managed farms stock feeding is reduced to a science here. "Co-operation" seems to be the watchword, and until we see our way to some sort of unity in England we must not be surprised to find the foreigner underselling us. The Government grants, too, in aid of agriculture are most liberal, and the people appear to be alive to their advantages.

We only hope Mr. Holm will make some other little tours, and give us the benefit of his further travel. He makes his outing profitable to himself and also to his readers.

WORK ON THE HOME FARM.

A matter which has been constantly forced on our notice during the last few years is the value of peat moss litter to the ordinary farmer. The dry seasons have, by minimising the crops of straw, increased the value and importance of bedding materials. Some farmers, when straw is scarce, never think of buying bedding, but let their cattle lie in a condition of filth such as almost requires the intervention of the Society for the Prevention of Cruelty to Animals. We have seen cattle tied up in a shed so close together that they could not lie down; as the owner said, "Straw was very scarce, and they kept cleaner standing." But is this true economy? We think not. However scarce and dear straw may be, there is no reason for farm animals being kept in a state of filth whilst peat moss litter can be bought at little over 20s. per ton.

We have tried it well under varying conditions, and have found it best when used as a foundation with a little straw on the top. This is particularly the case in the cow house, for here peat moss alone is too dusty, and is apt to get into the milk unless the cow's udder is carefully cleansed immediately before milking. For the cow house we prefer to have the gutter filled with moss litter, but the bedding should be straw.

For a covered yard, or for any yard in fact, a good covering of peat moss when the yard is empty—i.e., before stocking in autumn or after clearing of manure—makes an excellent foundation for the straw; it absorbs all liquids so readily that the straw put upon it is kept well drained, and lasts much longer.

We have had a short spell of frost; the weather is now again mild, and ploughs are at work. The frost enabled us to cart some manure on to old seeds, which we shall now plough 10 inches deep with chilled ploughs and skim coulter. The manure and turf will thus be well buried, and the land by March should be in good order for planting with Potatoes.

The mild weather has been very favourable for Turnips and Swedes, which have been growing all the time, and are now a good crop and likely to be plentiful after all.

We have been killing the usual bacon pigs, and if the pork trade would brighten up a bit should like to clear the spare ones, for pig corn is dear and Potatoes almost unobtainable.

REMARKS.

- 19th.—Dull and drizzly morning, and overcast after.
 20th.—Fair, but sunless till nearly sunset; clear night.
 21st.—Fair, but sunless.
 22nd.—Cold and dull early; faint sun all day, and bright for two or three hours.
 23rd.—Cold with slight fog, not entirely clearing at any time.
 24th.—Cold and foggy throughout.
 25th.—Foggy most of the day; evening fine, starlight, and thick white frost; from 10.30 P.M. to midnight exceptionally dense fog; street lamp invisible at 17 yards distance.
 Cold, foggy week with high barometer.
 26th.—Calm, frosty, and rather foggy; at 10.30 A.M. a sudden rise of temperature; afterwards dull and damp.
 27th.—Fine mild morning; dull afternoon; a little rain at night.
 28th.—Fair morning; sharp squall with rain at 2.45 P.M., very bright afterwards.
 29th.—Gale and squalls all day and night, with almost continuous rain from noon to 7 P.M.
 30th.—Squalls of wind and rain all morning; fair afternoon, with a little sun; fine night.
 31st.—Fair morning, with gleams of sun; alternate sunshine and showers after noon; complete primary and secondary rainbows at 3.15 P.M.
 1st, 1898.—Fine, but sunless.
 A mild and rainy week.—G. J. SYMONS.

BARR'S SEED GUIDE for 1898 IS NOW READY,

And will be Forwarded Free on Application.

Barr's Seed Guide for 1898 contains a select List of the best Vegetable Seeds and most beautiful Flower Seeds. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. *Sent free on application.*

Barr's 21/- Collection of the Best Vegetable Seeds contains 14 Pints of Peas (best successional sorts), 6 Pints of Beans (Broad, French, and Runners), and a liberal Assortment of other Vegetable Seeds, for One Year's supply. *For full particulars see Barr's Seed Guide, free on application.*

Barr's 10/6 Collection of Choice Flower Seeds contains a liberal selection of the most beautiful Annuals and Perennials. Full particulars in Barr's Seed Guide, in which will also be found many sterling Novelties for 1898.

All Seeds sent Carriage Paid on receipt of remittance.

A DAY IN OLD ORCHARDS.

SOME little time ago I was invited to examine five orchards on an estate about thirty miles from London, and advise on the renovation of the trees, or such of them as were amenable to improvement. It is well to make the best of old trees that may be induced to bear useful fruit, if only of second-rate value, until young trees, which should at the time be planted, are capable of yielding a supply of high-class produce. A brief description of the several orchards, coupled with the advice that was given to their owner, may possibly be useful to others, and with that object this little narrative is prepared.

Orchard No. 1.—Soil evidently good, and grass luxuriant. Only a few relics of canker-eaten, moss-laden Apple trees stood here and there in the body of the ground; but across the end were trees which had not lost their vigour, but in varieties worthless for consumptive purposes.

Advice.—The quickest method of obtaining a supply of excellent fruit would undoubtedly be by making a clearance of the whole of them, except those previously alluded to as being in fair health. The others were practically beyond renovation, and would certainly not pay for time and material expended on them. The end trees of worthless varieties were advised to be cut down, the stems limewashed, and have several grafts of Bramley's Seedling Apple inserted in them in the spring. This is one of the best restorative varieties in existence. Its innate vigour and powerful leafage prepares and deposits organised matter so plentifully as to in no long time cover ancient and even cankered stems. This I have seen in Nottinghamshire and elsewhere, and no doubt any number of scions may be obtained from Mr. H. Merryweather of Southwell, who tells us in his advertisements it is the "best Apple on earth."

Young Trees.—The enclosed site is well adapted for a cultivated fruit garden established on either of the following methods:—

A.—Planted with bush Apples on English Paradise stocks (also a few Plums and Pears if desired); trees 8 feet apart in rows 10 feet asunder

of free bearing and moderately compact (not the most robust) growing varieties.

B.—Planted with low standard trees, of similar varieties, 12 feet asunder. Strong growers should be 15 apart, having in view their eventual development.

In either case, Strawberries, Raspberries, and Black Currants, or such vegetables as Potatoes, Onions, or other root crops may be grown between the rows for a few years, but not to encroach upon them, or to involve interference with the fibrous roots of the trees by digging.

C.—Orchard standards, medium growers 24 feet apart, robust growers 30 feet, on prepared stations in the grass.

Soil Preparation.—For methods A and B the whole of the ground should be bastard trenched—i.e., working it two spade or fork depths, but not bringing the under soil to the surface. Line out a space 2 feet wide, remove the soil to a full spade depth, or a foot including shovellings; thoroughly break up the bottom to a similar depth, not leaving the soil in large chunks. Set out the second trench of exactly the same width; chip off the grass, and place it on the broken up bottom soil, removing fleshy rooted weeds. Spread on the strip from which the grass and weeds have been removed 1 lb. of basic slag (for giving lime and slow acting phosphate), with a little less than half that quantity of kainit (for potash) on a length of 6 yards = 18 feet by 2 feet, and well mix with the top soil in turning it over on the grass in the trench. If this is well sprinkled with lime first, making it quite white, it will be advantageous.

The mixing of the minerals applied is better done by digging with forks, taking small spits or slices, than with spades taking wide ones. If a large heap of wood ashes can be obtained by burning refuse, including all the portions of old trees that can be so reduced, this will do instead of kainit for giving potash, and may be spread on half an inch or more thick if sufficiently plentiful. Treat the whole ground as advised and it will grow fruit trees, bushes, and root crops. The soil taken from the first trench will fill in the last.

Stations in the grass for trees should be similarly prepared, and 5 or 6 feet in diameter. Plant carefully after the soil has settled, pruning all broken ends of roots smoothly; spread these out evenly in layers with soil between, and do not sink the stems the least trifle deeper than they were before the trees were taken up. Press down the soil moderately, stake the trees if needed, without injuring the bark. Spread littery manure over the ground; rake it off when the sun attains sufficient power to warm the soil to incite root extension, and mulch with closer manure on the approach of hot weather for keeping the soil moist near the surface, and for the retention and multiplication of roots there. Cut off two-thirds of the long strong shoots of the newly planted trees (the roots of which have been much shortened in the process of digging up) when the buds commence swelling in spring, but any short and weak branches leave unshortened, as the terminal buds of these will be the first to produce leaves and summon the roots into activity. In due time the weak parts should be removed, as the better growths from the stronger shortened stems will form the basis of the tree. Proceed on the lines indicated, and a thrifty fruit plantation will be established.

Methods A and B would cost much more than C, but give substantial results far sooner and pay much better in the course of a few years, because in the latter case a great extent of ground would be wasted (or devoted to growing grass), while by the alternative plans it would be utilised in the production of fruit or other serviceable crops. Under the management of a competent gardener the first method (A) would be preferable; the second (B) is simpler, and after some years bearing every other tree could be removed, if thought desirable, the remainder standing 24 feet asunder, and the land laid down to grass.

No. 2 Orchard.—Centenarian or bi-centenarian trees, which can no more be made healthy bearers of superior fruit than an ancient decaying Oak can be reinvigorated, or a hard-worked, ill fed, actually worn out thirty-year-old horse can be made young and strong again. It is a patriarchal orchard, picturesque, but cannot be made profitable. Nor can the planting of another on the same site be advised, for the trees

during all those years of occupation have practically exhausted the soil of fruit-growing constituents. If a new orchard were desired it would be far cheaper to establish and give much better results in a new site. Of that there can be no doubt whatsoever. Notes on the above orchards must be postponed.—ADVISER.

SIMILARITY OF LIFE IN THE VEGETABLE AND ANIMAL KINGDOMS.

ON THE BORDER LINE.

In placing the two great kingdoms in juxtaposition, it is possible that whilst taking a bird's-eye view of the whole of vegetable life our vision is foreshortened in turning to the animal kingdom, and we are apt to look little beyond our own species or the higher forms of life immediately beneath our notice. *Apropos* of this, Charles Bennett, a naturalist, wrote, "We can only judge of things by comparison, and have taken our ideas of animal life from the larger animals. . . . How many facts are ignored which will come one day to derange our ideas of subjects which we think we understand! At present we know just enough to be aware that we should be surprised at nothing."

In approaching so vast a subject, so vast, indeed, that one may well pause on the threshold in contemplating the infinite phases of created life, the most comprehensive survey that the mind is able to take, or the farthest that human thought is able to travel, must fall short, not of desire, but of accomplishment to do it justice. Certainly the most this paper can pretend to do is to show some salient points of similarity between the two kingdoms, with the hope, a vague one at the best perhaps, that it may strike the keynote to a more harmonious understanding of the beauty and the subtlety of this silent life, and that a bond of sympathy may be established between those who labour in the great field of Nature and the objects of their care to the attainment of the best results.

Going back to the very border line, which, indeed, presents so little in the way of demarcation that Crabbe—who wrote at a time when the twin physiological studies exercised the minds of some of the most brilliant savants of that or any day, and whose poetical effusions, if somewhat crude, have at least been accredited with the characteristics of force and accuracy—in expressing the difficulties met with says:—

Involved in sea-wrack here you find a race,
Which Science, doubting, knows not where to place.

This, however, is in allusion to those forms of life, the Polyps, existing in water, which have since been relegated to the animal kingdom. One is, perhaps, inclined to ask why such stupid beings that vegetate rather than live, deficient in all the organs which we generally associate with life in the animal kingdom, should be placed in it? We can take a parent Polyp, make him, or her (it does not matter which), into cuttings, each cutting developing into the perfect plant—no, animal—with the same facility with which we may propagate the common Stonecrop by chopping it up and sowing it broadcast. There is really no intention of questioning the rights of these extraordinary creatures to the position given to them by Science, but one could hardly fail in commencing to observe how narrow is the border line between the two kingdoms.

THE SENSIBILITY OF PLANTS.

Ere briefly touching upon this interesting phase of our subject the opinion of two high authorities may be adduced. Dr. Lindley, in his general considerations upon vegetable physiology, says, "The analogy that undoubtedly exists between plants and animals is most striking." And Professor Asa Gray remarks, "The spores and other reproductive bodies of many of the lower Algæ may claim to have first a characteristically animal and then an unequivocally vegetable existence." It is not surprising that even such an ardent pupil of Nature as the great Linnæus should go a little astray in tracing the hidden paths, for we find him formulating his diata defining the then called "Three Kingdoms of Nature" as follows:—"Minerals grow; vegetables grow and live; animals grow and live and feel." In a sense only is the growth of minerals now recognised, such bodies increasing by aggregation or superposition, by mechanical or chemical agency. Travellers who followed the tracks of this great pioneer have come to this conclusion, and few will now question the correctness of it; and they, too, have done something towards discovering the missing link—the break—which Linnæus thought sufficient to distinguish between the two great kingdoms of life.

We have yet, possibly, the faintest glimmer of light to show that feeling, as represented by sensibility to touch, exists in plants; but we have that, and who shall say what the search-light of science may yet reveal in the silent life of the sister kingdom, or to what depths

the present darkness may be illumined? Darwin's observations upon twining plants lead to the inference that they possess in a distinctly perceptible degree the faculty of feeling. This we may admit in noting how the bine or tendrils of certain plants grope blindly, as it were, for an object of attachment, such object only requiring to be brought in contact with the sensitive tentacular-like growth than it is at once appropriated, pretty much the same as the cuttlefish, whose instinctive sensibility certainly goes no higher in the scale of intelligence in those cases where it has been known to grip in its tentacular embrace the anchor hanging from a yacht and retain its grip until dismembered.

With the plant sensibility to touch is apparent, for the growth, whose spiral tendencies have hitherto lain dormant, at once displays its inherent power. Tendrils of the Vine illustrate this in a marked degree, sufficient as it is to overcome the tendency of most vegetable growth, particularly that of twining habit, to an upward direction; the tendril being able to perform its functions on a horizontal wire, and to which every semi-revolution has of necessity a downward inclination. Should the tendril, however, in its course meet with any appreciable decline below the horizontal plane it will double back upon itself and travel the easier road. More delicate observation has revealed a sensibility to touch in plants of a totally different habit—the Oxalis, for one. Results of investigations into this phase of plant life by Morren and Hofmeister have been confirmed by Darwin. This is quite apart from the very pronounced examples afforded by such plants as the Mimosa pudica or the Dionæa muscipula, whose sensibility can be favourably compared with many of the lower types of life in the animal kingdom, and even with some of a higher grade whose insensibility to pain disproves the theory that they "in corporal sufferance find a pang as great as when a giant dies."

In proof of the latter and in disproof of the quotation, we have the experience of the entomologist Haworth, who in catching a dragonfly accidentally severed the long abdomen from the rest of the body, and presenting a fly to the mutilated insect, it was immediately seized and devoured; a second fly being treated in the same manner. The dragonfly upon being set at liberty, in Mr. Haworth's words, flew away with as much apparent glee as if it had received no injury." One is inclined to digress with remarkable examples in which the heart, brain, and stomach have been removed, whilst life has existed for months after, but sufficient has, perhaps, been adduced to show that we place too high an estimate upon sensibility in the animal kingdom to the depreciation of plants, which are voiceless to express any feeling they may have; and which, of course, ordinary observation says they have not. This remains to be proved.—INVICTA.

(To be continued.)

FAIR DEVON.

(Continued from page 569.)

CIDER production was no doubt the chief object in view when most of the older Devonshire orchards were planted, but as that industry has declined, and the fermented juice of the Apple has ceased to be the popular beverage it was in former times, the plantations have lost their importance in the eyes of farmers or occupiers of the land. Dr. Bull of Hereford has traced back the origin of the greater portion of orchard planting in England to the end of the seventeenth century, when Continental wars stopped the importation of foreign wines, and it became "an object of national importance—a patriotic duty—to encourage the home production of cider and perry." Enormous quantities of this beverage were made which were consumed in a correspondingly liberal manner, for the workmen were allowed practically as much as they could drink, which is said to have been in many cases $1\frac{1}{2}$ to 2 gallons each per day. Indeed "experienced" cider drinkers are even now pointed out to the curious in such matters, who are capable of disposing of 2 gallons in a day. If the decline of such habits were the only matter in connection with the failing of the Devon orchards there would not be much to lament; but while in the early days only varieties having a reputation for special qualities were planted, in later years many worthless seedlings have been allowed to take their place, until we search in vain for the Apples which were once so celebrated. For example, the Coccagee was at one time as celebrated in Devonshire for producing the highest quality of cider as the Foxwhelp has been, and still is, in Herefordshire, but in my journey I did not succeed in finding a single specimen of the variety which was known to be true. It is procurable from a few nurserymen, but is little known amongst the farmers.

Good cider is, however, still made in Devonshire, and though I tested many brands that were undeniably poor, a few were excellent, and quite equal, in my estimation, to the light wines of France and Germany. In really first-rate condition, cider is both wholesome and pleasant, but the liquid ordinarily sold to the public under that name is simply a libellous counterfeit. If some enterprising business man,

with plenty of capital at his disposal, could discover a new and taking title for cider, could produce a high quality brand, and advertise it largely, there might be a fortune in it, even in these times.

The remark of my travelling companion has led to rather a long and rambling letter, but it must not be concluded without a word respecting the great charm of Devonshire, its varied and picturesque scenery. Certainly it is one of the most distinct and delightful of our English counties. It has not the ruggedness of Derbyshire, yet one can find all the wildness desired on dreary Dartmoor and amongst its towering "Tors," while the succession of hills and valleys, with the rich luxuriance of vegetation, everywhere provides abundant attractions for the lover of Nature. As a holiday resort it is not surprising that "Fair Devon" has gained so much fame, and thousands of those who annually seek the attractions of other lands might find in this charming county all that the most exacting can desire. To the horticulturist it also presents abounding interest in the numerous fine gardens and collections of trees. Even in searching for the wild plants, especially the Ferns, many a pleasant day could be spent. A popular writer (a Devonian) says, "We have found Blackberries in some of the valleys that would compare favourably with the Mulberries of many favoured climes, and the Raspberries of the most carefully tended garden. Passengers sitting on the top of the coach have gathered wild Raspberries in hedgerows fine enough to excite the envy of many a market gardener in the Midlands, some of the southern counties too." I was not fortunate enough to see any of these wonderful productions, but what I did see (perhaps even more remarkable) shall be described in another contribution.

That fruit is grown successfully in Devonshire, visitors who explore the beautiful valleys which extend along the boundaries of the counties of Devon and Cornwall in the direction of Plymouth, are afforded very surprising proofs. The charmingly picturesque River Tamar winds its way to the sea through deep valleys, the hills on each side rising to a considerable height and extremely steep, at some places, in fact, almost precipitous. A large portion of these slopes is occupied with Oak coppice or Fir plantations, but extensive areas have been cleared at intervals and are devoted to a very different form of cultivation. The first time I had the pleasure of travelling through the Vine-growing districts of France and on the borders of Switzerland or Italy, nothing impressed me more than the height and steepness of the slopes clothed with Vines, and therefore subjected to the art of the cultivator. In some cases it seemed almost impossible that men could work on land at such an angle, or that strong-rooting plants like the Vine could obtain sufficient hold, for one would expect the soil to be washed away as fast as it is formed. It is true the Devonshire slopes cannot equal either in height or steepness the approaches to the alpine regions of the continent, but there are portions of the River Tamar district which in these characters are not surpassed in England.

Strawberries may be seen flourishing in many different soils and under very different conditions. I have had them on heavy land but slightly removed from clay, and I have had plantations on soils of the other extreme—namely, those nearly approaching to sand, in which it would never be expected that these plants could grow in any degree satisfactorily. Yet, making allowance for the different behaviour of some varieties, profitable crops have been had from both. It has been more than once recorded in this Journal what exceptional success has been obtained in the neighbourhood of Virginia Water in the cultivation of Strawberries on what appears at first sight to be little more than a sand-bank. The soil of the Devon and Cornish hills is not so light as that, but it is in many places much lighter than would be regarded generally as favourable to Strawberries, yet there they are, not in a few hundreds, but in many thousands, covering spaces varying from a few square yards up to 20 or even 30 acres. That the plants are thoroughly at home is evinced by the fine healthy foliage, and more substantially to the grower by the abundant crops produced.

It would be difficult to estimate the extent of land under Strawberries in the neighbourhood, but there are certainly some hundreds of landholders almost entirely occupied with their cultivation. Many of the smaller growers do all the work themselves, with the aid of their families, and some additional help at fruit-gathering time; they even occupy themselves during the winter in the manufacture of the punnets, and the boxes employed for packing the latter in, thus saving a few shillings in their expenses. One successful worker informed me that they can purchase sufficient chips to make a gross of punnets for 1s. 6d., but if they buy them ready made they cost 2s. 6d. per gross. As the larger growers require many thousands of these, the local manufacture of the punnets is quite a home trade for winter.

The punnets are, however, different from those we are accustomed to see in the London markets or the northern towns, which are supplied

from the southern counties. Though considerably to the advantage of the grower in point of size, and convenient for packing in boxes, they do not appear to be well adapted for such a soft and easily damaged fruit as the Strawberry. They are too deep in proportion to their width, and being slightly contracted at the top, which does not allow the fruit to be seen to the same advantage as in shallower punnets. The average size is $2\frac{3}{4}$ inches deep, $4\frac{1}{4}$ inches in diameter at the top, and $4\frac{1}{2}$ inches across at the bottom, and they therefore do not hold anything like a pound of fruit. As most of the fruit is for early sale, and by far the largest quantity is disposed of in punnets at good prices, it must be a very profitable way of distributing the produce. A grower who has steadily advanced from small holdings to one of about 30 acres, sends away 10,000 punnets on three or four mornings a week in the height of the season, or a total of about 150,000 punnets in good seasons, and he employs from 100 to 140 gatherers, who come from Plymouth and neighbouring towns.

The land cleared of Oak coppice, I was assured, is the most satisfactory, and it is said that the Fir plantation land does not yield nearly such good results, even when the soil seems in other respects more suitable. The general method is to clear the ground gradually, grub up all the roots, plough, give a heavy dressing of manure, and then take a crop of Potatoes, which have a beneficial preparatory effect on the soil apart from the cleansing. The "manure" which is almost exclusively employed is obtained from Plymouth, and appears to be nothing but the refuse collected from streets and dustbins. This costs £2 10s. per barge load of 30 tons, and it is estimated that owing to the cost of carting and spreading on the steep slopes the total cost is about £5 for the quantity named, which may be distributed over 1 acre to $1\frac{1}{2}$ acre. A few of the more enterprising have tried artificial or chemical manures, but they do not seem very much impressed with the results, though one or two speak favourably of basic slag applied in heavy dressings for Strawberries, Raspberries, and Cherries.—VIATOR.

(To be continued.)

HARMFUL AND HARMLESS GARDEN MOTHS—14.

AMONGST the moths that are bred in gardens, or come to them as visitors, the great majority are of small size, belonging to the Geometer or Tortrix group, or to the numerous division of "tinies," which, though diminutive, have often such splendid colours. Of the moths with stoutish bodies that are on the wing during the twilight or all night long, most are members of the Noctua group, insects which are easily recognisable as a brotherhood even by those who are no naturalists, though the separation of individual species is often puzzling. Light offers no attractions to them, as it does to the species of some other families; but sweet substances, in flowers or elsewhere, do not fail to draw. It is with the object of ensnaring them that the collector spreads upon tree trunks or palings his cunningly mixed compounds, the recipes for which vary. Usually it is made of treacle or the coarse sugar called "foots," and the solution is flavoured by a dash of rum, perhaps a little oil of aniseed. Gardeners might follow the same plan to reduce the number of sundry species which, in the caterpillar state, do a considerable amount of mischief some seasons. Such a preparation, when it is more convenient, may be used as a bait by wetting rags or pieces of cloth with it and hanging them up.

Passing along a flowery border or bank on a summer evening, after sunset, with a lantern, it is a pretty sight to watch parties of these moths eagerly helping themselves to the honey by means of their long spiral tongues. Sometimes, in their anxiety to get to some coveted blossoms, they push each other unceremoniously, their eyes frequently sparkling like diamonds or tiny stars. (What produces these gleams of light is uncertain, I can hardly think they are of a phosphorescent nature.) But this is singular, upon a bright moonlight evening we seldom see such moths on the wing, or, at least, only a few stragglers. The majority of Noctuas exhibit dull colours; some of them have conspicuous tints, especially on the lower pair of wings, which are then covered by the upper pair when the insect is reposing. Nearly always the body is thick, and the down upon the thorax rises into a sort of crest. During the day, these moths sit with folded upper wings, sometimes upon the earth, or amongst low herbage, others select walls, palings, and trunks of trees as a place of rest. Frequently the colours of the moth harmonise with the object selected, the resemblance being so close that persons occasionally place a hand upon some moth unawares, only discovering the fact by the soft feel.

The habits of the Noctua caterpillars vary; some of them are to be found all the year under or on the earth, from which in winter they are dislodged by the gardener now and then, also by the birds. Of those that are about in the spring and summer many feed at night principally. To this division of insects belong the bulk of the destructive army of surface caterpillars which direct their attacks to

the crowns and underground stems of plants, not merely injuring but often killing. Mostly they are smooth, stout, of dull colours, with trenchant jaws; if alarmed they roll into a ring, feigning death. A few live between the folded leaves of trees. In the group of dagger moths the caterpillars are hairy, and feed chiefly on trees or shrubs. Amongst the Noctuas only there occur two or three species that might be said to be friendly to horticulture, for their caterpillars are partly cannibals, sucking at times the juices of others. Sometimes the chrysalis is enclosed in a cocoon attached to a branch or twig, but generally it is placed under the soil at a moderate depth; it is black or dark brown, and glossy.

In those good old times, when handsome butterflies and moths were sought for the purpose of making "pictures," so called, the Peach-blossom moth (*Thyatira batis*) was looked upon as a prize. Occasionally it is discovered in gardens, having flown over from a hedgerow where the Bramble afforded food to the caterpillar during autumn, the English name having reference to the adornment of the moth, not to any harm done by the insect to the Peach. Upon the upper wings are arranged five spots, the edges of which are white and the centres rosy or reddish brown; their shape might suggest pink petals, but scarcely those as large as the Peach. No doubt this tint led to the selection of the generic name, that of an old city famed for its purple dyes. The caterpillar is curiously humped, and holds on to the twigs with the middle legs, the head and tail being raised in the air.

Where the graceful Birch adorns lawns, shrubberies, or avenues, it often supplies food for some caterpillars of the Noctuas called the satin or lutestring moths, from the glossy appearance of their wings, which are rather ample for the size of the body; they form the genus *Cymatophora*. Of these we may take as a sample *C. duplaris*, which flies in the evening about midsummer, occurring through most English counties. The wings are smoky grey, with a few white marks, and some darker lines. It is the habit of the caterpillar to spin together two or three leaves of the Birch, but it does not eat these, using them for shelter only. At night it issues forth to devour neighbouring leaves, then returns to its home; if alarmed it runs out of this backwards.

Quite a contrast in size to the preceding species is the little moth known as the marbled beauty, or *Bryophila perla*. It is one of the species that are particularly abundant near the metropolis. For an obvious reason suburban gardens are more frequently protected by walls than by hedges or palings, which give but poor security, and upon these walls, when they have obtained some age, flourish numerous flat lichens, which the moist atmosphere of London suits well. Upon these the caterpillars of this moth feed, usually at night. Sometimes they appear to have a fast, for when the lichens are dry they are unpalatable, and the caterpillars remain still in the small abodes they have made. I have seen both stone and brick walls studded with these moths for weeks between the middle of July and the end of September; there is probably a succession of them. Winter they have indeed, but they seldom travel any distance by their aid; they are pale grey, often suffused with green, also having spots and lines of a darker colour. Many gardeners must have noticed these moths, since they are observable in parties at times, resting on the walls, and it is worth while during these winter months to look again along them, where the caterpillars are now hibernating. Hatched from little pearly eggs in October, they feed a few weeks, then conceal themselves within crevices of the bricks and mortar, spinning silken cocoons. If the weather is mild they come forth in February or March and eat the lichens of spring, chiefly at morning and evening. Each has his house, composed of fragments off the wall or particles of earth, which the caterpillars unite with silk, these abodes resembling a portion of the wall; in these, when the weather is warm and dry, they remain for days secreted. Allied to this is a less common species, *B. glandifera*, or the marbled green, of similar times and habit.

There is a family of moths styled the wainscots; their caterpillars mostly select for food grasses and reeds of a variety of species. In gardens near streams or fields, they are occasionally found by day sheltering amongst low plants. One species at least may do us a good turn, this is the oddly named brown-line bright-eye; it has brown lines certainly, and a very conspicuous white mark on the fore wings. In science it is the *Leucania conigera*. Its period of flight is July, and it is distributed over Britain. From autumn to May the caterpillar, which is brown, black, and yellow, feeds upon grasses, being especially partial to that annoying species, the couch or spear grass (*Triticum repens*). One of the prettiest of the wainscots is the clay moth, *L. lithargyria*; the colours, though not particularly bright, are shown in delicate lines and spots upon a reddish-brown ground. Also we notice some beautiful tints in the common wainscot, *L. pallens*, rather lighter in colour, which occurs from June to August. The caterpillar lives on grasses for eight or nine months. One of the abundant moths along the course of the Thames, near London, used to be the southern wainscot (*L. straminea*). The home of the caterpillar was in the reeds, but of late years it has been scarce.—ENTOMOLOGIST.

LÆLIA ANCEPS VIRGINALIS.

As the issue (January 20th, 1887), containing the illustration and note relative to this charming Orchid has long been out of print, we reproduce it here (fig. 5) for the benefit of "D. B. C." and others. According to the note which accompanied the woodcut it was sent to South Kensington from Mr. F. A. Philbrick's choice collection at Bickley. The description was as follows:—It is remarkable for the great size of the flowers, which are 5 inches across, the petals being nearly $1\frac{1}{2}$ inch across, of great substance, and pure white. The lip is broad with a yellow throat. In contrast with the richly coloured forms of *L. anceps* that are so useful at this time of the year this variety appears to excellent advantage.

CALANTHES.

MUCH has been written in praise of these beautiful Orchids, and in establishments where table decorations are extensively carried out their use has become almost indispensable in the winter season. Too much cannot easily be said in their favour for table work. *C. Veitchi* is especially much admired; the long sprays thrown carelessly on the cloth or arranged lightly in vases, their elegant arches of flowers considerably enhance the appearance of the dining tables of the well-to-do. I know of no prettier effect than a well-arranged table decked with these flowers intermingled with a small amount of Fern or Asparagus, with bright shining *Smilax* as a set-off to the whole. It is also well known how suitable they are on the plants for mixing in groups with Ferns and other suitable kinds. One of the best small groups I remember seeing was composed chiefly of *Calanthe Veitchi* with Roman Hyacinths and Ferns, set up with pieces of cork and moss as an imitation rockery. The effect was really charming, and not nearly so artificial looking as one might on first thoughts suppose.

A good deal has been said against these deciduous *Calanthes* because they lose their leaves at flowering time, though I do not think this is made so much of as formerly. Really, from a gardener's point of view, this characteristic has its advantages, and though admiring the plants very much myself when they are in full growth, I think where space is a consideration—and where is it not?—the gain through being able to stand the pots nearer to each other when the leaves fall amply compensates.

A few remarks as to culture may not be out of place. After the plants have flowered they may be stored in any out of the way corner where drip does not reach them, and the temperature does not, as a rule, fall below 55°. There they may rest until March, when upon signs of starting into growth preparation should be made for potting. The pots may be of various sizes, from 5-inch to 7-inch, according to the size of the pseudo-bulbs and the number in each pot. I consider medium-sized pseudo-bulbs are calculated to give a better return where the spikes have to be cut than those of extra large size. I say nothing against these latter as specimens of good culture, but two or three smaller spikes of useful flowers may be grown in the room of one of extra size, and will in most cases be found more suitable for the table. Have the pots clean and well drained, with some moss or rough turf over the crocks to prevent blocking. As to soil, some growers use only turfy loam with the finer particles shaken out. A good compost found to grow these plants fairly consists of turfy loam with about a third peat and a sprinkling of sand, with the addition of a very small proportion of well-decayed sheep or cow dung.

The old plants may be shaken out of the soil, and if desired to increase the stock, those which have produced flower spikes can be packed rather closely in pans or boxes and placed in strong heat, when a number of them will break and produce small pseudo-bulbs, which ultimately should be grown with the others. Those remaining of the current year which have to produce the flowers in the future should have their roots shortened to about an inch, and be potted firmly. For a time they will need very little water, a slight moistening with the syringe occasionally sufficing, and as growth increases so must the supply of water. When the pots have become full of roots weak liquid manure made from sheep or cow dung may be given once or

twice a week, according to requirements. Give water plentifully from the time the plants have made fair growth until the flower spikes appear. As these lengthen gradually diminish the supply, and by the time the first flowers open no more will be needed before the plants are ready to start again in the following March.

It has been advised to lay the plants in boxes in leaf mould or damp moss in preference to potting at once. I have tried both methods, and while admitting that the former has advantages, yet I prefer the latter, as when the pseudo-bulbs have emitted rootlets into the layering material, which they do freely, it is almost impossible to avoid breaking some of them in potting, as at this stage they are exceedingly brittle.

Calanthe Veitchi and the charming Rangmore variety, with the varieties of *C. vestita*, may be grown in the usual stove temperature, kept close to the glass and shaded from excessive sunshine. Evergreen *Calanthes* and their culture do not come within the scope of this article.

Thrips, green fly, and brown scale all attack *Calanthes*, and are best kept under by gentle sponging. The disease known as spot I have not had to deal with. It is possible this may sometimes partly

FIG. 5.—LÆLIA ANCEPS VIRGINALIS.

arise from high feeding, the plants afterwards being stood in cool damp conservatories and cold draughty rooms. This should as far as possible be avoided. The difficulty may be met where a number are grown by frequent changing.—J. SHALFORD.

REST IN PLANT LIFE.

IN "A. D.'s" last note on this subject he is silent on the point as to whether plants rest or not, so presumably he concedes it. Now, it is the term itself he takes exception to; but if not absolutely correct, it is not a bad one after all. "A. D." says, "rest implies recuperation." Certainly; and that plants recuperate themselves during the cessation of growth is abundantly evident. Plant physiology is a delightful study no doubt, but mere workaday observation is all that is required to prove this. Defoliation is only a detail. Evergreen trees rest as well as deciduous ones, and though perhaps I may be dense, I fail to see why we as cultivators need the term to be any further "described, explained, elucidated."

In its practical sense as bearing on cultivation I understand it, so does "A. D.," or he is not the sound practical gardener his writings have for many years proclaimed him. Would a Vine go on producing Grapes without rest? or would any other plant fulfil its functions without it? I think everyone must agree that they would not. If not, why not? Something is wanting that was present at the end of the last resting season. This the plant makes good during its season of rest, hence I take it there is recuperation going on.—H. R. R.

VEGETABLES FOR HOME AND EXHIBITION.

RUNNER AND BROAD BEANS.

It would be difficult to over-rate the value of the Runner Bean, which, being hardier and later than Dwarf Beans, makes an excellent succession. In order to assist the plant to do its best during the long season in which it crops, recourse should be had to deep cultivation with an ample supply of manure to sustain the lower roots. An abundance of fine pods which find favour both on the show board and dining table may be obtained by taking out the soil two spits deep and about 2 feet wide. Good farmyard manure should be dug in at the bottom of the trench, and the soil with one layer of manure a spit below the surface be replaced. The plant then has a deep rooting medium of enriched soil, in which its fibres may ramify and supply the support necessary for its welfare under the strain of pod production. In seasons of drought the benefit of this method of cultivation is particularly apparent.

Runners do not readily lend themselves to any methods of forcing, but in order to encourage them to come in early they are sometimes sown in boxes or pots close to the glass in cool frames in April, and transplanted later in the rows. In sowing for removal soil of a fibrous character should be chosen, so that this adheres to the roots, and the Beans can be transplanted with balls of earth attached. Generally speaking, the first week in May is early enough to make the sowing for a main crop supply, and if the soil has been previously prepared as recommended above a broad drill some 3 inches deep should be drawn out, and the seeds inserted zigzag fashion about 6 inches apart. Many growers sow the seeds in two rows, and insert the poles at a slight angle, lashing them together when they cross at the top. An argument raised against this method is that when the poles are furnished with foliage the ground between the rows is invariably dry, as the rain naturally drips from the leaves to the outer side of the rows. When rows are sown parallel to each other a distance of 8 to 10 feet should be allowed between them, and where a large quantity is required two successional sowings ought to be made at the end of May and middle of June.

When the plants are about 6 inches high the soil should be drawn up to them from each side with a hoe, and the poles inserted. These may be kept from swaying by tying laths or other poles along them horizontally, 6 or 7 feet from the ground. No stopping of the growth is necessary, though it is important that the pods on the lower part of the stems be picked as they mature, in order to encourage those higher up to develop. During hot dry weather water is frequently necessary, particularly on light soils, and if a mulching of littery manure or short grass follow the operation the moisture given is largely conserved.

Growing runners without sticks is a system chiefly adopted by market gardeners and others who have a difficulty in getting the necessary poles. Under this method of culture the rows may be dispersed about 3 feet apart, and the growths kept regularly pinched. One of the drawbacks is that the pods are frequently splashed during wet weather, but this may be averted by mulching between the rows with any material of a littery nature. There are many named varieties of runners, and amongst them Royal Jubilee, Giant White, Ne Plus Ultra, and Prizewinner will meet the requirements of both exhibitors and home growers. Long straight pods of even character are the best for exhibition, taking care to choose only such as are in the best condition for table, and will readily break under pressure of the thumb and finger.

It is not necessary to enlarge on the cultivation of the Broad Bean, as the plant is one of ready accommodation when conditions of culture are fairly favourable. Drought is the most frequent cause of failure, and during the past summer we have had ample opportunities of noticing this where the soil was of a shallow, sandy nature. With deeply worked soil of a sound texture and well enriched with good manure, Broad Beans rarely disappoint us. The taste for this vegetable appears to vary very much, though as an article of food there is but one opinion as regards its nutritious qualities. The Longpod varieties are the most suitable for the early sowings, which should be made thinly at the end of February or early in March, and of these both the Early and the Seville Longpods are good. The rows must not be less than 3 feet asunder, and the plants to supply large pods fit for exhibition purposes should be allowed a distance of from 9 to 12 inches apart. In order to keep up a succession sowings ought to be made at intervals, the Improved Broad Windsor being one of the best for main crop and late use. Beck's Gem is an excellent dwarf variety, and is much appreciated, as the beans are small in size and of a delicious flavour. This variety may be grown more closely.

Black fly is the common enemy of the Broad Bean, and insecticides are frequently used in destroying it. As, however, the plants are not often attacked until the crop is insured the most efficient way of getting rid of the pest is to pinch out the tops of the plants and destroy them. A moist position should always be chosen for this crop, and in order to prolong the season in dry weather, and assist the

production of large pods, supplies of water and liquid manure must be given. For exhibition purposes the best pods are long and filled with tender beans placed closely together. Some varieties produce pods large enough to please anyone, but the beans are dispersed so widely apart in them that many have to be pulled to make a dish. Needless to say such kinds are not the best to grow. All pods of Broad Beans should be removed from the plants as they mature, whether required for use or not, otherwise the formation of others higher up the stems will be checked.—GROWER AND JUDGE.

A GOOD INVESTMENT.

AN APPEAL TO THE "MISSUS."

THE money market is not, judging from what one knows, a matter of primary concern to the great gardening fraternity. The rise and fall of stocks in the horticultural world are chiefly limited to those particular varieties known as Bromptons, East Lothians, or Ten-weeks. Yet few men better know the value of money, I venture to say, than gardeners, and fewer still are more cautious in their calculations in an honest endeavour to make both ends meet; but meet they do, with a long pull and a strong pull, and all praise to many a good "missus," who, doing a lion's share in the tug-of-war, finds, when the ends have met, a remnant over. And she will know what to do with it. But in the way of a good investment our better-half is not above receiving a good suggestion, and such I have to make. It has been made before, but never to the "missus," and herein laid the mistake. At least that inference has been reluctantly arrived at because the prior suggestions have fallen flat. Should some lord and master of a gardener's frugal home think that any insinuation is here implied anent what is vulgarly termed petticoat government, so be it. There is not, I believe, any finer form of home rule, or could we on the broader basis desire any more beneficent example, than that afforded by the Lady who has ruled so long, so wisely, and so well over the destinies of the Empire.

On the occasion of a friendly visit to a neighbour, as we sat over the cup that cheers, I was particularly impressed with the shrewdness of his "missus" when the conversation drifted from "Mums" to money. My friend, producing a glowing prospectus, said, "I think I'll have a few shares in this; what do you think?" What I thought was of but little moment, seeing that the "missus" forestalled me by saying, "No! my money shall never go into that," with a strong emphasis on the negative and a decided inflection upon the possessive. Not too strong or too decided, however, as events proved, for what was shady when floated soon shook to pieces. So the "missus," as chancellor of my friend's exchequer, scored, to the admiration of him who has now a "real good thing" to place before her and all the gentle spirits who rule so wisely.

The Gardeners' Royal Benevolent Institution, dear "missus," is what I commend to your notice, to your shrewdness, and to your good sense. If you will but digest the statistics of this noble Institution, now generally well known, in your well-balanced mind, I have no fear but what the good man, willy-nilly, will be a Royal Benevolent gardener, and to you be ascribed the honour and glory. The notice, now to hand, of the annual general meeting to be held on the 20th proximo, states that nineteen pensioners are to be placed on the funds, ten of whom, having been shareholders in this grand investment scheme for a period extending over from fifteen to thirty-six years, are now to receive the benefits "without the trouble or expense of election." Good, as far as it goes, but it does not go far in noting that there are forty-four applicants remaining, nine only of whom can be elected according as the voters dictate, because the great body corporate of British gardeners simply ignore their plain duty of subscribing to and augmenting the capital chiefly contributed by those generous patrons of horticulture who, amongst the many claims upon them, so prominently recognise the wants of this Institution. The urgency of these forty-four cases, and the anxiety the applicants evince to grasp this prop in their old age, is obvious in scanning the appeal by post to members for their votes.

No need to analyse these pitiful appeals, or to say these people have only themselves to blame. There is not, I suppose, one of the forty-four who does not feel that, "To fail late in life is the worst failing of all;" not one but whose ease is far more eloquent than are any words of mine. There is, too, something pathetic in noticing that ten of these applicants are widows. It may be a natural feeling—or failing, which you will—that one's heart goes out to them in their lonely latter-days, and there is unqualified pleasure in voting for what one feels the most deserving case amongst them. Advisedly I say most deserving, for charity begins at home, and the good old gardener who has gone before, who recognised even late in life the claims of this Institution, surely deserved that preference should be shown by the endeavour to obtain its benefits for the "missus" bereaved.

One fact remains to be faced—viz., that the Gardeners' Royal Benevolent Institution is yet, practically, unsupported by gardeners, of whom there is not one who shall make with certainty that utterly selfish remark, "I shall never need it." So "Knowledge comes, but wisdom lingers." Yet the outlook is not wholly one of gloom in this direction. In the years that have fled this sound investment has not probably been so widely and generally known as its merits deserve, and I think, somehow, that the reports of its good work have oftener found their way into the potting-shed drawer among the plant and seed catalogues than to the gardener's cottage, where it would catch the eye of the "missus." To her I respectfully suggest at least further consideration of the above, relying upon a fair hearing, confident in her sound judgment, and last, not least, knowing that in the tender feelings of a woman's nature, "The quality of mercy is not strained."—A ROYAL BENEVOLENT GARDENER.

APRICOTS.

SUCCESS with the Apricot in England is by no means certain. Even in gardens, with careful preparation of borders and protection of the flowers in the spring, satisfactory results are more the exception than the rule. The great drawback to the culture of the Apricot is that of its being the earliest flowering of fruit trees, generally coming into blossom during February. But this cannot be regarded as the cause of failure in many gardens, for with efficient protection for the blossoms and tender fruit the trees are as notable for vigour as sterility; therefore, the cause of non-success must be looked for apart from the early flowering and the question of protection for the blossom.

The chief reason of failure in this country is, according to my experience, restriction, the trees never succeeding on low walls. On a wall of 10 feet height I once had what was considered the choicest varieties—Early Moorpark, Hemskerk, Kaisha, Moorpark, Oullins Early Peach, Peach, and St. Ambroise; the aspect south-west, elevation 500 feet above sea level, and the North Sea four miles distant eastward. The whole, duly protected with scrim canvas, kept from the trees by poles and drawn up or let down as required, bore well whilst extending after the third year from planting as one year's trained trees: but when they reached the top of the wall, and covered their allotted space, every one except Kaisha began to bear less fruit, and in three years the trees were unprofitable. Indeed, the one tree of Kaisha gave more fruit than the other six trees put together: and whilst this remained healthy and fruitful the other trees, with the exception of St. Ambroise, began to lose their lower branches and a limb here and there from sudden collapse. On another wall, facing due south and 20 feet in height, were Blenheim or Shipley's and Royal, which, never protected, gave excellent crops. The difference could not be entirely due to the hardness of these as compared with the other varieties, but was a consequence of the adaptability of subject to place or *vice versa*. Thus Kaisha succeeded because it did not outgrow the space, also those on the high wall, and the others failed through their being pruned into sterility.

What I wish to impress by the foregoing is the futility of planting Apricot trees against low walls. Large areas of high, old-fashioned garden walls, the walls of stables, barns, outbuildings, and tens of thousands of cottages are the places for Apricots, where they will have a chance to produce enormous quantities of the most luscious of all hardy fruits annually. The climate is better now by drainage and other improvements than it was half a century ago, when Apricot trees were common on cottage walls, and the proceeds went a long way towards paying the rent; the walls of farm houses, and on the high walls of gardens, where it paid to use wool netting for protection to the blossom. Result, luscious Moorpark Apricots, 1500 golden fruits per tree of 36 feet by 13 feet.

SOIL.

If well drained, almost any garden soil will grow Apricots to perfection. It must be deep, a yard is not too much, not that borders need be made of that depth, but just take the soil as it is—a light, rather sandy loam, preferably, and stir it to such depth as will allow the roots to go into it without hindrance. Shallow borders—a few inches of ameliorated soil over chalk, or a hard pan or a stiff one, such as clay, are of no use for Apricots. They do well on warp, on sandy soils, especially alluvial silts, calcareous gravels over chalk not nearer than 3 feet—better 6 feet—and even on stony clays, always provided water does not lodge within 4 feet of the surface. Turn the soil, as in making compost, with the difference of keeping the good soil on the top, or if a loose soil, do not bother about anything but setting the tree, after adding some manure and turning under as for any other kind.

The thing is to select the soil as well as the aspect and space for this choice fruit, abandoning altogether the idea of making it conform to the wishes and requirements of man in any but a natural way. Making soil forestalls both principal and interest. This does not mean that a light soil is not all the better for draining to free it from the water running in quicksand at 3 to 4 feet from the surface, discomfiting Horsetails and Thistles, and rendering it suitable for Apricots. This, and adding road scrapings, lime rubbish, and burned clay to heavy soils, is different from making an excavation and bringing in fresh soil at great expense, or even moving soil 2 or 3 feet and adding substances improving of the staple, than clearing all away and often making a worse staple than that removed or would have been if properly treated by trenching and admixture of manure or other material. Such procedure has no bearing

on growing Apricots profitably, and does not enter into the calculations of growers of hardy fruits for market. A little, sometimes much manure, a turning, and attention to staple and draining, are all the points considered of importance as regards soil. No more is needed for Apricots.

VARIETIES.

Breda and Alberge de Montgamet are regarded as the only kinds that succeed as standards in the open air. Of this I have no experience; perhaps some correspondent will kindly say where Apricots as orchard trees may be found in England. Is it near the coast in the southern counties? On walls they bear freely, Alberge de Montgamet ripening at the end of July and Breda at the end of August, both small, and esteemed in the kitchen and still room. Such, however, are only wall space wasters outside private use, at least so I found, and if ever they are to profit it must be as standards—hence the query.

Blenheim or Shipley's, with Turkey, and even Royal, must be regarded as preservers, Roman being placed in the same category. For cooking and confectionery purposes they do well enough, but can hardly be considered, along with Frogmore Early, as equal to British market requirements except for the purposes named, and certainly not likely to meet much better fate than Plums grown against walls and also in plantations, as the public appetite requires whetting or educating to accept them on the score of profit.

This reduces the list to reasonable proportions, and even then it is questionable if Large Red and Large Early can be considered other than second rate. To name them is enough, and this reduction brings us to the Moorpark and Peach, for out must go the pointed-fruited St. Ambroise. Of Moorpark—needing no bush—we have Beaugé, a large rather late form: D'Alsace, a better grower, and not so liable to lose branches; Hemskerk, a good hardy sort; Powell's Late, unequalled for hardness, free bearing, and good quality, and Early Moorpark, a questionable yet good form, a little earlier in ripening. Of Peach, or Grose Pêche, Oullins Early seems to have a habit different from Moorpark, and though a little earlier does not beat the parent, Peach—the "finest of all" (Rivers).

From the two last forms of Apricots—the Moorpark and Peach—selection may safely be made, as none excel them, green or not over-ripe, for tarts, and for dessert are the only ones attaining the highest standard of excellence.

DISTANCE AND PLANTING.

An Apricot tree, if worth the name, will cover a large extent of wall area. Cordons imply narrow borders, root as well as top limitation, and only Kaisha is advised for that mode without it at 2 feet distance apart. For low walls—say of 6 feet height—plant dwarf fan-trained trees 12 feet apart. But that implies utilisation, there not being any reason why low walls, as well as high, should not give fruit according to the space. It should be remembered the Apricot does well in suburban as well in rural districts. By suburban is not meant the environs of manufacturing centres, but fairly open localities, where the sun is not obscured by smoke and the atmosphere laden with sulphurous and other fumes. It cares least of any fruit tree for the dust of roads, even relishing the sand.

Dwarf-trained are the best, but standards may be employed for walls where dwarfs would be liable to suffer, as against farm buildings to which cattle have access. Fan-trained only are suitable, and they are no better for being large. Evenly balanced branches, not too strong, are of far greater importance, the wood, being well ripened, having nothing to do with trees that are blemished in the wood—in fact, gummed—for it will follow them to the end of their days, and is the great cause of Apricot failure in England.

The roots must not, on any account, be allowed to get dry by exposure to the air. Nurserymen are very particular about this, using mats as the trees are lifted, in the packing shed, everywhere doing their best to make the trees safely endure the lifting and transference. The trees move well early in the spring, for though the blossoming be early the growth comes later; but the middle of February, or as soon after as the weather allows, may be regarded as the time to plant. Take out an opening large enough to receive the roots straight out, not making them fit the hole, for beyond cutting off bruised ends to sound wood, the more roots the better. Arrange the roots carefully, interlayering at all points with mellow soil, and not covering the uppermost more than 3 inches. Mulch to an inch in depth with good sweetened material. Avoid puddling, for ordinary soil in February is just in the right condition for favouring the emission of roots, and to get an abundance of fibres, meaning a good root formation at the start, is the foundation of future health and production.

If the trees are right, and the soil also, there will neither be any use for the knife or watering can for some time, and Apricots then and always show their detestation of the free use of the knife and misuse of the watering pot by producing nothing but leaves, and dying off limb by limb. The little pruning of the cottager and farmer just suits Apricots, and nothing pays so well on the south fronts of cottages and farm houses where the soil suits, as the trees like to push their roots deep into the earth and their branches high into the air, thus maintaining the reciprocal action essential to fruitfulness and health. Plant the trees and let them grow, doing no more than is absolutely necessary to cover the wall equally with fruitful branches from top to bottom. Indeed, to the cottager and farmer belongs the credit of the extension system as applied to wall trees, they always having abundance of fruit when trees on the low wall and restriction system were fruitless, the house being supplied with this fruit from the sources mentioned at remunerative prices.—G. ABBEY.

PLANTING.

If any planter has still this work to perform, and has had the privilege of empty ground, there must be some want of management, for never do I remember a season when there has been so little interruption from early October until Christmas week. The ground has been so warm, and worked so well in almost all cases, that Roses made a few roots at once. I have heard some remark that such early rooting was a decided disadvantage; that the young roots were almost certain to be killed, and would surely be injuriously checked by cold later on. Such is not my opinion. It is entirely different from when Roses are forced both top and bottom, and the former growth removed after roots have become far advanced; in that case great harm does undoubtedly accrue. But with our plants in the open we do not find it so; otherwise, instead of being an advantage to plant early, it would be just the reverse. We have long contended that if we could not move our plants early, and while the ground was still fairly warm, we would prefer waiting until spring. When planted in the depth of winter the roots remain so dormant that a frost or drying wind seems to abstract the whole of the moisture from the top growth. In early planted Roses this is replaced by young roots, as well as from the firmer settlement of soil around them. Another advantage lies in being more certain of procuring the desired varieties when purchasing from trade growers.

If there has been a season during the last twenty years when the wood ripened more steadily and efficiently than the present it does not occur to me. In no cases have we badly matured wood, and if only severe frost keeps off the more tender of our climbers should be a grand sight next summer. But these remarks may appear premature, so I will leave any more about our future prospects.

There is one hint I would like to give some amateur readers, and that is, Do not be in any hurry to prune outdoor Roses should they break into growth during the continuance of mild weather. In some notes upon Rose-growing for market purposes which appeared a few weeks back, I dwelt upon the advantage of bringing on plants in batches. Owing to the mild season those in pits and frames will be more forward than usual, and I would certainly place the second batch into heat a little sooner than would generally be the case.

ROSES UNDER GLASS.

Under glass our Roses are now demanding great attention, and will do so from this time onwards. All pruning must be completed at once, and any dry border in which Roses are planted should have a thorough soaking. Look over climbers, and see that no scale exists. By tackling these pests before young and tender growths appear, we can generally extirpate, or any rate greatly check them; whereas it is not possible to use sufficiently strong measures later on. Now we can use insecticide of double strength, and if the plants are trimmed of superfluous growth, and old leaves that may still adhere, it does not take long to go over the wood with a small brush. Use a little paraffin in the solution, and keep it well moved with the brush, then the mixture will not only work easier, but will cover more ground in less time and be more deadly. Half a pint will go a long way when so used, and very few scale will survive.

As other insects come along, which they are certain to do upon the appearance of new growth and the turn of days, be careful to take mild measures promptly. This applies to both syringing and fumigation. There are few more annoying disappointments in Rose culture than to find one has used too strong measures only a short time before a pleasurable crop would have been realised, and two applications of a weak and safe strength are more effectual.

Propagation by grafting should be in full work now. Those of our own, already done, have seldom looked better, and no delay in the work must be allowed if one is to realise a good plant for next season's use.

Because it is mild, I would not be caught napping in the matter of material ready to hand for protection in the event of a sharp frost. We know how suddenly these come on, and what a lot of work they entail at once.—PRACTICE.

THE PLUME POPPY.

THERE is a growing disposition on the part of many who are embarking upon the cultivation of hardy border flowers to demand an English name for the plants. Human nature is such that many persons, especially ladies, will even decline to purchase a plant with an unpronounceable Latin or Greek name. The Plume Poppy is not so unfortunate as many plants in this respect. Its botanical name of *Bocconia cordata* is easily negotiated, and there are few who cannot remember it. Yet there is something attractive about the English name besides the mere fact of its being in our own familiar tongue. This may lie in its alliteration. Whatever it may be, we find it a popular one, much more so than the other. Although the appearance of the plant at first sight does not dispose us to connect it with the Poppies, yet it is a Poppywort, and fairly entitled to the name, although the genus *Bocconia* differs from the others of the natural order by reason of its having apetalous flowers, followed by one-seeded capsules. I have also heard it called the Great Celandine.

In the "Index Kewensis" there are four species recognised as

belonging to the genus *Bocconia*, which was named after Paolo Bocconi, the Sicilian botanist, the author of the "Museum des Plants," and other works. *B. cordata* was separated by Robert Brown from the genus *Bocconia* on account of differences in the inflorescence, and in the number of seeds. The name Mr. Robert Brown applied to it was *Macleania cordata*, after Alex. Macleay, the Secretary to the Linnæan Society. It is now, however, again restored to its former place with the *Bocconias*. It is synonymous with *B. japonica* and *B. or Macleaya yedoensis*. It appears to have been introduced in 1795, and again in 1866. It is figured in the "Botanical Magazine," t. 1905, and in Maund's "Botanic Garden." It has also been frequently figured in the gardening press and other horticultural works. It is a native of China and Japan. The Plume Poppy is a fairly well known plant, and, indeed, it is in some localities becoming a very common garden flower. It is also a favourite exhibition flower with many, and is often very valuable in a large stand, where its elegant panicles of buff-coloured flowers frequently give a needed effect to the display.

It is as a border or wild garden plant that it is, however, seen to most advantage. Set well back in a broad border, or planted in a mass on the grass, or in the wild garden, its beautiful heart-shaped bronzy glaucous leaves, which are prettily lobed, and its graceful flowers raised aloft on stately stems, look exceedingly well. As Maund says in his "Botanic Garden":—"Exposed stamens alone, surrounding the ovary, form these airy flowers; thus, destitute of their legitimate apparel, a corolla, they have a light, graceful, and airy beauty, which, added to the peculiar rich bronze-tinted foliage, renders this plant a most desirable occupant of the herbaceous border." Its height varies according to the soil and position it receives, and it may be said to vary in general from 3 to 8 feet. I have seen it as much as 10 feet high, but this was in rich well-cultivated soil.

B. cordata is perfectly hardy, and increases rapidly by running at the roots. These runners, if taken off, will soon form flowering plants, especially if placed in pots when taken off during summer and grown on under glass. It does not appear to be too fastidious in its requirements, although only seen in full beauty in good soil and in a well-drained but fairly moist situation. It does not object to a little shade, but looks better in the sun. There has been lately introduced a variety named *B. cordata carnea*. The flowers of this have been described as of a pinky flesh-coloured tint. I have grown this, but regret that I cannot, in the meantime, speak very favourably about it. It may improve upon further acquaintance, but it seemed to me to be dull looking, and wanting the effect of the typical plant. Admirers of stately but elegant plants of distinct appearance would do well to include the Plume Poppy in their purchases when procuring new flowers.—S. ARNOTT.

HALL FOR HORTICULTURE.

A BEGINNING having been made by "D., Deal," towards the crystallisation of the actual requirements in relation to a hall for horticulture in this metropolis, the scope might be usefully extended. We have heard of space required for the Chrysanthemum Show alone, varying between the square yards obtained last autumn at the Aquarium and the extent of St. Paul's. It may be useful to the private purpose of the promoter of a St. Paul's idea to prove to his satisfaction the inability of getting away from the Aquarium, but there must surely be an approximate estimate obtainable from a more serious class of leading organisers of all the floricultural societies, if they will make an effort to give the figures required in useful dimensions for the contemplated future shows. The offices required for committee meetings, lecture room, and library could be had "upstairs," or on the ground floor of that portion of the hall not glass-roofed.

Mr. H. Cannell's figures *re* revenues, given a few weeks ago on page 606 of your Journal on this subject, might serve as a useful basis for the erection of buildings alone, leaving the question of freehold site to be discussed with full publicity. That the hall should be erected on the Thames Embankment by preference few will doubt, as it would admit of miles of private carriages and their affluent owners to become habitués at the new hall, so that the full extent of a series of floricultural attractions which the Committee may be able to bring before the well-to-do of our metropolis and provinces.

If thus the joint societies show their readiness to assist to their full ability, could not the figure for the possible freehold required be ascertained, not a fancy figure (asked) surely! but a serious limit be stated that might lead to business? If this figure be looked at by some of our wealthy citizens magnanimously disposed, would it be so utterly futile to see an advance made, and perhaps half the amount for the freehold offered by one or more men of wealth, on condition that the other half be contributed by the many well-to-do who spend their hundreds annually on their own private gardens and on cut flowers, and whose numbers, as members of the various floricultural societies, are increasing at a great rate, especially the last year or two? The said societies should each canvass among their own members, and outside *ad libitum*, and if there be any earnest in the love for flowers, surely this richest city of our globe could hardly continue to lag behind less favourably situated centres.

Expansion of revenue could be suggested from other sources for the new hall, and which might be discussed hereafter, and might mean some extension in wings of the building. Why, indeed, should the main hall not be let for exhibitions of all kinds acceptable to the Committee? which might mean quite an unexpected run of income, as such a situation alone would attract in an astonishing degree beyond what any other building in London could do. Indeed, promoters might do worse than reckon with this element in determining the dimensions.—H. H. R., *Forest Hill*.

WEATHER IN LONDON.—The second half of last week was perfectly dry, and though there was little frost, the weather was decidedly more seasonable. On each day the sun shone brightly at intervals, Friday proving particularly bright. On Saturday morning there was a white frost of about 5°, but it was quite warm later. Sunday was dull throughout the day, but no rain fell. Slight frosts occurred on Monday and Tuesday nights. Wednesday was dull and mild during the forenoon.

WEATHER IN THE NORTH.—The weather of the past week has been most unseasonable, dull and brightish days alternating, while a great deal of rain has fallen. Sunday was a sunny spring-like day; Monday very wet and gusty in the former part; and Tuesday morning, while fair, was dull, with the thermometer at 43°.—B. D., *S. Perthshire*.

ROYAL HORTICULTURAL SOCIETY AND THE VICTORIA MEDAL.—The Council having been consulted as to a proper mode of the use of the Victoria medal by members of the trade, have decided that the only permissible method is by the letters V.M.H. following the name of the holder of a medal. No other mention of the medal can be properly made in any publication pertaining to horticultural trade, or relating thereto.—W. WILKS, *Sec. By order of Council*.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—On Thursday, January 20th, the above Institution will hold a special general meeting to appoint two trustees, in succession to the late Dr. Hogg and Mr. J. Lee, who has resigned. At the same time the ordinary general meeting will be held, to elect pensioners to the fund, to transact the customary business, and to elect officers for the ensuing year. As usual the meeting will take place at Simpson's Hotel, Strand, at three o'clock precisely, under the presidency of Mr. Harry J. Veitch. The Duke of Portland has fixed Wednesday, June 8th, as the date of the fifty-ninth anniversary festival dinner (sixtieth year), at the Hôtel Metropole, of this Institution.

HARDY FRUIT CULTURE IN HUNGARY.—The cultivation of hardy fruits in Hungary has so greatly developed of late years that an official inquiry has been instituted with a view to ascertaining the number of trees and the number of varieties of the several kinds grown in the kingdom. But in consequence of a rumour having been circulated to the effect that the inquiry was being made for the purpose of taxing the trees, those engaged in the investigation experienced considerable difficulty in verifying the returns furnished them. According to a contemporary the statistical details are therefore hardly so trustworthy as could be desired. Subject to this qualification, the number of fruit trees enumerated in Hungary was 65 millions, of which 32 millions were Plum, and 14 million Apple and Pear trees. In Croatia and Slavonia 8,500,000 Plum trees, and 2 million Apple and Pear trees were scheduled.

EMPLOYEES' DINNER AND PRESENTATION AT CHELTENHAM.—On Friday night about seventy of the employés of Mr. J. Cypher, of the Queen's Nurseries, were entertained by him to a sumptuous dinner, prepared on the premises and served in one of the glass houses, which had been transformed into a dining-room for the time being. Mr. J. Cypher presided, and there were also present Mrs. and Miss Cypher, Mr. W. J. Cypher (Vice-Chairman), Mr. and Mrs. John Cypher, Mr. and Mrs. Frank Cypher. The dinner was partly in celebration of Mr. J. Cypher's seventieth birthday, and two presentations were made. These were to Mrs. Cypher and Miss Cypher. The former consisted of a silver-plated cheese dish and cover, bearing the inscription, "Presented to Mrs. J. Cypher by the indoor staff of the Nursery, January 7th, 1898," and that to Miss Cypher was a pair of massive alabaster vases, accompanied with a card on which was inscribed, "Presented to Miss Cypher as a mark of respect by the outside staff, January 7th, 1898." Mr. W. J. Cypher made the presentations on behalf of the men. Mr. Cypher responded for Mrs. and Miss Cypher, and assured them that as long as they lived they would appreciate and remember the kindness shown them. He further alluded to a present to himself some time ago of an easy chair, which he also appreciated and was very thankful for. During the evening harmony and recitations enlivened the proceedings, and amongst those who contributed to the pleasure were Messrs. Booth, Weaving, Radcliffe, Tilling, Jones, Clement, and Joyner.

CROYDON HORTICULTURAL SOCIETY.—We are informed that the summer exhibition of this Society will be held on Wednesday, June 29th.

DEATH OF MR. J. KENT.—I regret to inform you of the death, on Friday last, after many weeks' suffering, of Mr. John Kent, who for several years had been gardener to Mr. Francis Tagart. There were many beautiful wreaths and other devices, and much sympathy was shown for the widow and children.—W. STADDON, *Cote House Gardens, Westbury-on-Trym*.

CHESTER PAXTON SOCIETY.—The opening meeting of the above Society's winter session was held in the Grosvenor Museum on Saturday evening last, under the presidency of Mr. Barnes, when the opportunity was embraced of presenting Mr. G. P. Miln, the Hon. Sec. for the past eight years, with a gold watch and chain, as a grateful expression of thanks for the services he has rendered the Society during this time.

DEVON AND EXETER GARDENERS' ASSOCIATION.—Mr. W. Charley presided and Mr. C. H. Clark occupied the vice-chair at the annual supper last Friday evening at the Castle Hotel of the members and friends of the Devon and Exeter Gardeners' Association. The Chairman said the Society was established to promote the mutual improvement of its members, and to advance horticulture. The Society had succeeded in a remarkable degree. It had not only made a good name for itself in this city and county, but its good work had been recognised by competent authorities elsewhere. Nearly every branch of gardening and its allied subjects had been touched on at the fortnightly meetings, and many of the papers read bore the hall-mark of excellence, and must have been of benefit to the members.

WALL TREES.—When I looked in upon Mr. J. Miller at Ruxley Lodge Gardens on a mild afternoon of last week I found him busily engaged in drawing nails from his Peach and Nectarine trees, that the young wood might largely fall away from the wall, the buds already showing too much evidence of excitement. Mr. Miller, who is one of our oldest gardeners in harness, remarked that very likely many gardeners were busy nailing their trees up. He, however, saw that if the mild, open weather continued there was every probability that bloom would expand fully a month too soon, and he regarded unnailing as far more effectual in checking early expansion than any other course. Some may let down their canvas shelters, or clothe the trees with Fir or Laurel boughs, but these things often in weakening the buds do more of harm than good. He thought nothing was so likely to retard development as the simple plan of unnailing the wood.—A. D.

GRAND YORKSHIRE GALA.—Last Friday night the annual meeting of the guarantors and life members of the Grand Yorkshire Gala was held at Harker's Hotel, York. Alderman Sir Joseph Terry occupying the chair. There was a good attendance. The Chairman, alluding to the Gala in June, said that circumstances had prevented the public witnessing the usual beautiful floral exhibition. He believed the flower show would have been of an exceptional character, and one which would have been immensely appreciated. A strong wind, however, on the morning of the fête wrecked the flower tents, and rendered all the perfected arrangements but work in vain. The damage done amounted to about £600, a catastrophe which had never been previously experienced. On every hand the circumstances had created regret. Expressions of sympathy had been received from several of the exhibitors, and one gentleman—Mr. Atkinson of Sheffield—had sent a donation of five guineas to the Society. As regarded the coming fête, they had again made satisfactory arrangements with the Bootham Asylum authorities. Other pleasing circumstances were that the Lord Mayor (Mr. Edwin Gray) and the City Sheriff (Mr. Harold Copperthwaite) had been elected life members, and the Lord Mayor had consented to become President for the current year. Sir Joseph Terry was unanimously elected Chairman of the Council, and Mr. Border re-appointed Vice-chairman. The other officers appointed were:—Treasurer, Mr. Joseph Wilkinson; Secretary, Mr. C. W. Simmons; and Auditors, Messrs. Pearson and Taylor. The following members were elected on the Council:—Alderman Sir Christopher A. Milward, Messrs. R. Anderson, G. Balmford, J. Blenkin, J. Biscomb, J. W. Craven, M. Cooper, H. C. Day, Alderman Dale, G. Garbutt, T. G. Hodgson, J. J. Hunt, A. Jones, G. Potter-Kirby, E. B. Kendall, T. M. Lambert, Alderman Purnell, E. S. Robinson, H. Scott, W. S. Sharp, and J. B. Sampson, with Alderman Clayton and Councillor Foster. The following grants were made for the ensuing Gala:—Floral arrangements, £650 (including £50 as a Victorian commemoration prize, offered last year, but not awarded); music, £200; fireworks, £100; amusements, £150; balloons, £60.

— **DEATH OF MRS. G. SPRINGTHORPE.**—A wide circle of friends of the esteemed gardener at Coombe Court, Kingston-on-Thames, will feel for him profound sympathy on learning of the sudden death of his wife, which took place early on the morning of December 30th. Mr. and Mrs. Springthorpe had led a very happy wedded life of seventeen years. Five children are left, four of which are quite young. The calamity has brought deep sorrow into what was so recently a very happy home.

— **CAMPHOR IN AUSTRALIA.**—The Camphor flora, it is well known, grows very freely in these colonies. The increasing demand for camphor for use in explosives and in the manufacture of celluloid gives greater importance than ever to this commodity. The Japanese commenced to prepare it by distilling the leaves and branches of the trees instead of destroying only full-grown trees for the purpose. It seems to be worth while to ascertain if the shrub growing in the warmer climates will bear cutting sufficiently well to yield an adequate return of camphor when distilled.—(“Chemist and Druggist.”)

— **THE CANNA DISEASE.**—In a recent bulletin of the Trinidad Botanic Gardens it is stated that one of the new strains of Canna imported for the Gardens has been badly attacked by a yellow rust called *Uredo Cannæ*, described as a parasite on Cannas from Brazil. Bordeaux mixture seems to have had no effect upon the fungus, and the infested plants soon die. This disease has not hitherto been heard much of, but if its virulence and deadly character are not exaggerated it soon will be. Meanwhile, we have no doubt that stringent measures are being taken to limit as far as possible the sphere of its operations, otherwise the queenly Canna will be in some danger at what is practically the beginning of its horticultural career.—(“Gardening World.”)

— **CISSUS BERRIES.**—The berries of *Cissus Ampelopsis* of the Middle and Southern States are most remarkable as well as beautiful in colour, clear pink, purple, rich blue, and an almost emerald green occurring in the same cluster. The botanists describe them as bluish, bluish or greenish. They much resemble those of the Chinese species, often cultivated in this country for its beautifully coloured fruit, and are not less beautiful; but while in the latter the prevailing colour is a rich Nile blue verging to emerald green, purple, and pink shades, especially the latter being exceptional, the reverse is true with the American species, in which a delicate lilac-pink is the predominating hue. Like the blue berries of *Cornus circinata*, the berries of this climber, which in the forest completely covers large trees with a luxuriant drapery of foliage, are a favourite fruit of many kinds of birds, particularly the catbird, brown thrasher, wood thrush and flicker, and on this account, if no other, should be grown by all lovers of birds. The fruit of *Cissus* stans, another southern species, is also very distinct in its colouring, the extremely glossy berries, the size of peas, ranging from light pink, through garnet, red and dark crimson to jet black. The elegant pinnate foliage of this vine is unique in its peculiar dark bluish-green colour, the upper surface of the leaves having a semi-metallic lustre.—(“Garden and Forest.”)

— **ROYAL BOTANIC GARDENS, CALCUTTA.**—The magnificent Gardens across the Hooghly River have been ruled over by a long line of illustrious botanists—botanists whose reputations have been world-wide. Wallich, Roxburgh, Griffith are names which recall the early struggles of a science to establish its roots in the East and spread its branches. Dr. George Kiug, the retiring Superintendent, has, perhaps, done more to popularise and extend the usefulness of the Royal Botanic Gardens, Calcutta (or Seebpore, to be more exact), than any of his illustrious predecessors. He has ruled over its destinies for many years. The early struggles of the writer of these lines in endeavouring to master the subtle intricacies of Lindley's classification of certain “alliances” of “perigenous exogens,” of De Candolle's natural classification, and the complicated artificial classification of Linnæus, are all associated in his mind with the name of Dr. George King, to whom he is indebted for much of his botanical education. Dr. King will be succeeded by Dr. David Prain, who has for several years held the post of Curator of the Herbarium of the Royal Botanic Gardens, Seebpore, where he has done excellent work. No better selection could have been made, and we congratulate Dr. Prain on his appointment and the Government of India on their sagacity in putting the square man into the square hole for once. Dr. Prain is an erudite scholar and a high authority as a botanist. He is the author of several learned botanical monographs, and we have every confidence that under his rule the Botanic Gardens will continue to extend their usefulness in the future as they have in the past under the guidance of the genial and learned gentleman whom Dr. Prain succeeds.—(“Indian Gardening.”)

— **A GIGANTIC FOSSILISED OAK.**—An influential deputation of geologists waited upon the Sewage Outfall Committee of the Stockport Corporation, and presented a petition, asking that the gigantic fossilised Oak tree found at Cheadle Heath might be preserved. Professor Boyd Dawkins has estimated that the tree is between ten and fifteen thousand years old. It is desired to preserve the 40-ton fossil in bulk, or turn it into furniture for public buildings.

— **THE QUEEN AND KEW GARDENS.**—The Queen has decided that the old Palace at Kew shall be opened, during her Majesty's pleasure, as a public museum, under the same management as Kew Gardens; and by her wish the grounds belonging to what is known as the “Queen's Cottage” will also be utilised in connection with the Royal Gardens, a very attractive addition being thus made to the Gardens, the amenities of which are enjoyed by the public.

— **ROYAL METEOROLOGICAL SOCIETY.**—The annual general meeting of the Society will be held, by kind permission of the Council, at the Institution of Civil Engineers, Great George Street, Westminster, on Wednesday, the 19th inst., at 7.45 P.M., when the report of the Council will be read, the election of officers and Council for the ensuing year will take place, and the President (Mr. E. Mawley, F.R.H.S.) will deliver an address on “Weather Influences on Farm and Garden Crops,” which will be illustrated by lantern slides. The above meeting will be preceded by an ordinary meeting, which will commence at 7.30 P.M.

— **DECEMBER WEATHER IN SOUTH WALES — HEAVY RAIN-FALL.**—Mr. W. Mabbott, The Gardens, Gwernllwyn House, Dowlais, Glamorgan, writes:—“The weather here during the past month has been worthy of this record-breaking age. Total rainfall 13.34 inches, a monthly record. Maximum fall, 3.30 inches on the 29th, a record for any twenty-four hours; previous record 3.18 inches in November, 1895. There were six daily falls of over an inch during the month, which is another record. Rain fell every day from the 5th to the 16th inclusive, and from the 26th to the 31st. Rain fell on nineteen days. Total for the year, 63.42 inches. Mean maximum temperature for the month, 42.9°; highest reading 53° on the 17th; mean maximum, 30.5°. Lowest reading 13° on the 1st; below freezing point on fifteen days. Very strong cold winds the beginning of the month, but towards the end of the month much milder. Ten sunless days during the month, 106 during the year.”

— **IRIS RETICULATA.**—This is a hardy plant, but requires, to grow it well, a warm corner and a bed of pure light sandy loam; in the ordinary soil of an old flower garden the bulbs are apt to rot. This and many other small hardy bulbs will generally break up into offsets and dwindle under pot cultivation. The commonest Crocus or Tulip will do the same. Grow the Iris as I have described; take up and store in dry earth or sand when the foliage dies down, and select the best bulbs to flower in the greenhouse; in the autumn restore the bulbs to their old quarters. They will come round again after one season's growth. The Peacock Iris should be grown in the same way, but absolutely requires a glass frame over the bed. Pot culture is, however, possible for such plants, and I recommend the following treatment: Use rather large pots—say 8 inches across; soil, very sandy pure loam; drainage, one or two large crocks with a good large handful of moss over them. Put in plenty of bulbs—say 2 inches apart, grow them in a good cold frame through the winter, and bring them into the greenhouse in the spring to flower.—R. C.

— **LOUGHBOROUGH AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—The opening winter session of the above Association took place on January 4th, Mr. J. Lansdell of The Gardens, Barkby Hall, Leicester, giving an interesting and instructive lecture on “Soils.” The lecturer, speaking of the formation of soils, referred to the constant action of the atmosphere and rain, which caused something like 1 foot of soil to be washed from the hills towards sea in the course of a thousand years. In proof of this, statement Mr. Lansdell handed around some samples of Mountsorrel stone (the hardest kind of stone in this county) which had become quite pulverised and amenable to cultivation. Clay soil was referred to as being the outcome of felspar rock—the best garden soils should contain about fifty per cent. of clay. The lecturer dealt with the different colour of soils, their analysis, and the mechanical operations necessary to add to their fertility; quoting statistics as to the beneficial effect of draining to promote vegetation, by creating a higher temperature in the land, thereby making it admissible to nitrogen, the principal agent in the cultivation of vegetable life. Mr. A. Hamshire presided over the meeting. A hearty vote of thanks was accorded the lecturer and chairman.

— MY GARDEN DIARY.—A copy of this admirable little Diary, which is published by Messrs. Sutton & Sons, Reading, has just reached us. It is really surprising how much valuable information of a wholly practical nature they have been able to condense in such small compass, and the book ought to be of assistance to everyone engaged in the garden. Each month has its calendar of operations given clearly and concisely, the facing page being left blank for notes that will be useful for future guidance. The paper is of excellent quality, and the printing of the best. The motto that has been adopted for the book, "Doing things in good time is the main secret of successful gardening," is full of meaning, and embodies the essence of truth.

— ESPARTO GRASS IN ALGERIA.—According to a report issued by Mr. Scratchley, the British Vice-Consul at Philippeville, Algeria, a strong feeling growing in that country has arisen against the importation of "Alfa" into England. "Alfa," "Sparto Grass," or "Esparto Grass" (*Stipa tenacissima*), is a plant which produces a paper more supple, yet with more resistance, than that made from other plants. It is mainly used by our manufacturers in making *papier de luxe*. Out of 709,546 cwt. of Esparto exported last year from Algeria, over 664,000 cwt. came into England, and our manufacturers have practically had the monopoly of this article since 1863. The chief reason for this monopoly has been that in the manufacture large quantities of chloride of lime are required. But this difficulty has now disappeared, since electricity has been introduced as a bleaching agent. The probability is, says a contemporary, that the Algerians will now establish manufactories of their own in Philippeville, and thereby create a profitable industry of an article which, in France at least, would find a ready sale. Last year over 7,000,000 acres were covered with the plant. The difficulties likely to arise are scarcity of water, lack of fuel, and insufficient railway communication.

— SPANISH CHESTNUTS.—The nuts of the so-called Spanish Chestnut form a considerable proportion of the unenumerated fruits imported during the autumn months, and large supplies are sent us from France and Spain. The French Chestnuts are ready for sale earlier than those from other countries, and consequently hold the market at the outset. The bulk of the French crop is exported, and being the first to arrive here the nuts realise a better price, and then the dealers supply themselves from Italy, from which country they import as much as 50,000 cwt. annually. The Italians, however, are making efforts to establish a direct trade with England. A contemporary says that their chief difficulty hitherto has been that the nuts are apt to germinate, and thus become unfit for the market. A method of checking this germination is said to have been discovered, and is stated to be carried out in the following way:—The nut is soaked for seven or eight days in a tank and well stirred daily, after which it takes about a week to dry again. This seems to sterilise it completely, and in this condition it can be exported satisfactorily. It is a remarkable fact that if a second lot of Chestnuts are put in the same water they will be sterilised in about half the time. This season a large quantity of the Italian nuts have been placed on the British market.

— FRUITS ON ARCHES.—I observe the new issue of the Royal Horticultural Society's "Journal" includes your part representation of Mrs. Chrystie's Gooseberry trellis at Great Bookham, Surrey. I have often thought, even before seeing this trellis, because of the capital trellises I had some time previously noted at Claremont, that excellent results might be obtained from wire arches clothed within with either single or treble cordon Gooseberries and Currants. The trellises at Claremont are about 3 feet apart. That would be too narrow for an archway, but 5 feet width should do admirably. It would be needful to have the supports of iron wire, and at intervals of about 9 inches pierced with holes, through which the wires could pass, these being firmly secured at either end. A trellis of 5 feet wide at the base should rise in the apex to a height of 6 feet 6 inches. The bushes should be planted on the inside, and about 12 inches apart. Then it would be desirable to select fairly strong and equable growing varieties, so that furnishing might be pretty much alike. A footpath should run through between the cordons, but it would be best that it be of the ordinary soil trodden and raked fine, and if desired, could be strewn with long straw litter during the fruiting season. There is no reason to assume that ample light and air would not penetrate to the cordons, and mature buds as well as ripen fruit. Planted as advised, all the fruit would hang beneath, and with netting thrown over on the outside, the whole of the fruit could be admirably protected from the birds. Once well in fruit, and carefully pruned and manured, the plants would produce such fine crops as would soon repay the first cost of the archway and planting.—A. D.

— TUBERCLES ON THE ROOTS OF PEA PLANTS.—Some experiments have been conducted at the Louisiana Experiment Station, U.S.A., with the view of ascertaining the influence of deep and shallow planting upon the root tubercles of Pea plants, the depth to which the nitrifying germs penetrate, and the results of transferring them to different host plants. The field Pea was planted at depths varying from 1 inch to 6 inches, and the root system was best developed in the case of plants from seeds placed at 2 inches or 3 inches from the surface. Pots were filled with soil taken at depths varying from 1 foot to 3 feet, but tubercles were found in relatively small quantities only on those plants grown in soil not more than 12 inches below the surface, the rest having no tubercles. When the surface was artificially inoculated with germs, root tubercles were produced in abundance. The experiments, says a contemporary, also go to show that each species, or at most each genus, of plants, has a different microbe peculiar to it.

— HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—At a meeting of the above Society, held on Tuesday, January 4th, Mr. F. Mason, gardener to Alex. Smith, Esq., Woodleigh, Hessle, read a comprehensive paper on the "Forcing of Flowering Plants." Commencing with describing the most suitable kinds of houses for early and late forcing, he passed on to the forcing of bulbs and roots, classifying them in the different varieties most suitable for succession, also the method of cultivation. Then he referred to the multitudinous varieties of flowering trees, shrubs, and Roses, arranging them in the different positions according to the amount of forcing required. The excellent discussion that followed the paper brought forth the suggestion that a spring show should be held in connection with the Society, where a great number of forced flowers could be seen to advantage, a suggestion that we hope will be carried out, and would, no doubt, meet with every success. Mr. G. C. Coates, gardener to W. Wheatley, Esq., Anlaby Road, Hull, showed some good blooms of *Chrysanthemum Dennis Smith-Rylands*. A vote of thanks to the essayist and Chairman terminated the meeting.—G. W. G.

— APPLE STIRLING CASTLE.—For dwarf trees especially I cannot recommend a more suitable Apple than this. It appears to me to have all the good qualities of the Hawthornden—earliness, productiveness, high culinary quality, and compact growth, yet without the proneness to canker which renders the Hawthornden unsuitable to many soils. Were I planting dwarf trees largely with the view of deriving the earliest profit by the sale of their fruit, I should certainly have a good number of Stirling Castle. In a long row of trees in twenty-five varieties, the three which have proved the most valuable by their free and constant bearing, and the excellence of their produce for culinary purposes in the autumn, are Lord Suffield, Stirling Castle, and Cellini, coming into use in the order named. I am scarcely able to say which of these three I have found the most serviceable for home use. For travelling the Stirling Castle is the best, not bruising so much as the others named. The soil of the garden is rather light, and Hawthornden cankers excessively. In this soil Stirling Castle requires no root-pruning and but little summer-pinching, but grows into a natural and fruitful bush which anyone can manage. No better recommendation than this ought to be required by amateurs.—B. B.

— ARE BANANAS BENEFICIAL?—In an exchange we read, says the "Tropical Agriculturist," that a boom in Bananas, baked Bananas, has been started in the United States, the well-known fruit being now said to be an "ideal food" for the nervous, the anæmic, and for brain-workers. Strange to say the raw fruit is said to be dangerous, as it contains "germs;" but when baked it acquires properties never heard of before. In this country we cannot get Bananas in perfection; but they have them in fine condition in New York, to which city and other places on the Atlantic seaboard they are quickly transported from the Bahamas. Fruits of *Musa paradisiaca* and *M. sapientum*, the Banana and the Plantain, have long been known as a staple article of food in tropical countries, where they are cultivated just as the cereals and the farinaceous tubers are in temperate regions; in fact cultivation has produced considerable variety in form, colour, and flavour. Humboldt and Boussingault estimated that in a suitable climate, and well cultivated, a Banana plant will produce on an average three bunches of fruit weighing 44 lbs. each per annum, and that in hot climates more than 130,000 lbs. of good food could be grown per acre—an amount greatly in excess of the yield of Potatoes, which are, moreover, said to be less nutritious. That has, however, been disputed; but all travellers and investigators aver that the Banana is an excellent food baked, roasted, fried, or boiled. In this country bunches weighing as much as 80 lbs. have been grown in hothouses.

CHRYSANTHEMUM EARLSWOOD BEAUTY.

THE craze for immense Japanese Chrysanthemums appears to have put the more homely single varieties completely in the background, and a good collection is comparatively seldom seen. This is certainly a matter for regret, as few flowers that are at command in the winter are more graceful or more useful for decorative purposes than these. For light, elegant arrangements they are really admirable, and fortunately they last in good condition when cut and placed in water for a very long time. The natural result of this neglect is that raisers of new Chrysanthemums pay only a small amount of attention to them, and new varieties are consequently not often seen. Of the few that have been shown this season, Earlswood Beauty, of which we give a photographic illustration, ranks amongst the very best. The flowers are large, the ray florets being of great substance. The colour is white with faint blush suffusions towards the tips of the florets. The raiser was Mr. W. Wells of Earlswood, to whom we are indebted for the photograph.

THE N.C.S.—THE SLAVE OF THE AQUARIUM.

RECENTLY, through the assistance of your columns, I attempted in clear and courteous language to convey to your readers the impressions I then felt, "That the N.C.S. was not holding its own in the furtherance of its objects as the premier Chrysanthemum Society against the rapid strides and successes gained by several provincial centres."

Writing, as I did, on my own initiative, I did not anticipate the large amount of support and congratulations which have followed in corroboration of the views to which I so reluctantly gave expression. The result has been most encouraging, and clearly establishes the fact that a strong feeling exists throughout the country against holding exhibitions of the finest collections of cut blooms and plants in a building so thoroughly unsuitable for the purposes of artistic arrangement and effect as the Aquarium has proved itself to be. This has been admitted by every writer with the solitary exception of Mr. Richard Dean.

These expressions of opinion should be sufficient to convince Mr. Dean that there exists a very large amount of public dissent against the continuation of the Royal Aquarium as the home of the N.C.S., and to warrant him in assisting his Committee in seeking for a more desirable quarter, and if not found to report fully to the supporters of the N.C.S. the result of their labours.

I have carefully read all that has appeared for and against the present abode of the N.C.S., and find, as others must have found, that not one of your correspondents has so strongly set forth the utter weakness of the Society on the lines it is now running as its own Secretary has; and the many reasons and obstacles he so freely put forward in favour of continuing its present policy only prove most clearly, and beyond all contradiction, that the Society as now constituted is the slave of the Aquarium authorities, and is at present unable to wrench itself from its grip.

I will not attempt to follow Mr. Dean in all the praises he has indulged in favour of the Aquarium Company and its privileges; but unfortunately for him his views are so strongly in opposition to all others, and these he "floats so gaily aloft," that the whole context of his exultations, instead of making a favourable impression, has the opposite effect of exhibiting the weakness of our present constitution when he says "that without the co-operation and valuable assistance furnished by the Directors of the Royal Aquarium the National Chrysanthemum Society cannot exist." Fellow workers, there is food for contemplation. Are you content with the humiliation?

I am no ultra-purist or sentimentalist, but delight in "mutual converse, warmth, light, and life," and I hope I shall not be accused of egotism when I say that I am well versed in a large number of the varieties of Chrysanthemums that have been in cultivation for upwards of thirty years. Our "champion" and I met as exhibitors at Southampton in 1880, and I had a successful career as an exhibitor previous to that date, while at the present day I am responsible for a very large public display, which is usually open daily for seven or eight weeks, so that I do not write without some knowledge of the flower and acquaintance with arrangement and effect.

Grand blooms have hitherto found their way to the Aquarium, and the Society has been able to hold its own in both quality and quantity, but of late neither a satisfactory arrangement nor proper effect has the N.C.S. been able to contribute to the "devotees who worship at its shrine." Through an inability to furnish these important elements the Society must in time lose considerable status, and then will both quality and quantity of blooms, together with subscribers, rapidly diminish.

What a soothing and lasting effect any novelty in artistic arrangement has on public opinion. As an instance of this, the neat arrangement of cut blooms with table and berried plants, first commenced at the early Kingston exhibitions, is now adopted by nearly all our local and provincial shows. The magnificent and artistically arranged groups first instituted at Hull are influencing exhibitors throughout the country, and are fast ousting the formal packed groups which used to be so con-

spicuously set up with sticks and pots so glaringly visible as to largely detract from any pleasing effect.

The encouragement of pleasing styles in beauty and effect is as necessary for the "premier" Society to cultivate for arousing "new-born interest" as is the offering of substantial prizes for the best flowers. Any Society which through force of circumstances is unable to combine all these elements in its exhibitions cannot impart the useful knowledge which its votaries look for, and should rightly receive.

It does, indeed, seem strange, if true, that in London with its vast populace, amongst which can be found as many lovers, growers, and enthusiasts of the autumn queen as in any other part of Great Britain, that a society founded solely for the purpose of promoting its cultivation cannot exist without a yearly subsidy furnished by another organisation whose objects and interest are, in comparison, as wide apart as the North and South Poles.

During the past two decades has the "National" swung on the same pivot? Where there was one grower in its early days there are now hundreds, and I might say thousands, and yet this Society, with all its boasted progress, is utterly unable to do that which nearly every local and provincial society can do, and is doing, from the Land's End to Aberdeen—namely, holding exhibitions purely by their own strength and paying their way.

The "National," with all the "assistance and co-operation" received from the Aquarium Directors can only boast of about £100 reserve fund.

If this crutch is necessary to prop us up, would it not, I ask with all seriousness, be more prudent to hold fewer exhibitions for a time in order that we may be able to put aside that which would make us more really independent when the crisis came, which sooner or later, if we continue in our present fettered state, must come?

Mr. Dean prides himself on four exhibitions, but as to the September show, as I said in my previous letter, the Committee knows very little of its working. In the N.C.Society's report for 1894 I find the following:—"Arrangements have been made with the Royal Aquarium Society to hold three exhibitions in the present year as in 1893—in October, November, and December," and in the report for 1895, "The Committee have arranged for the holding of three exhibitions at the Royal Aquarium during the months of October, November, and December; and a Dahlia show will be held by the Royal Aquarium Society in September, as heretofore, at which prizes will be offered by this Society for early Chrysanthemums, and these will be supplemented by a grant of £10 for Dahlias."

These early flowering Chrysanthemums, however much I admire and cherish them for displays out of doors in the autumn, are scarcely suitable for an exhibition, when, at the time they are in flower, there are a host of other flowering plants far more striking and attractive, and the £20 odd awarded in prize money at this show, together with the grant of £10 towards the Dahlias, would be far better serving the object and purposes of the National Chrysanthemum Society if placed to the reserve fund or even added to the prize list for the November exhibition. It would then at least be awarded in accordance with the objects of the N.C.S.—the sole encouragement of raising and cultivating the Chrysanthemum.

That amount of £30 represents the subscription of 120 members, which is a consideration, and should be well weighed before receiving the approval of the Committee in making the grant for the forthcoming season.

From the report it does appear that in London there is a difficulty in finding a more convenient home than the present one; but no one during recent years has tried to find a place, and after the expression of opinion made by several eminent persons at the Hotel Metropole, it was clearly the duty of the Committee to have taken some steps, and reported the result of their labours at the annual meeting next month.

The Agricultural Hall has been named. During the recent cattle show I questioned myself on the point, and could not help feeling that if it could be got at any reasonable terms, it would, to all appearance, make an admirable place for our November exhibition. No one spot in London will be central from and to everywhere, but every place is considered central where, from a railway terminus, a cab can drive direct to the place for a shilling or two. The difficulty and dislikes to a building is when a cab is taken and then another transhipment has to be made for a short distance by rail to the destination.

In the early part of this letter I referred to the congratulations I have received. Besides receiving numbers personally, other gentlemen have written from the provinces as follows:—"I must thank you for your clear letter in the *Journal of Horticulture* last week re the National Chrysanthemum Society. For several years I have thought the Committee ought to have run the shows on a good business basis."

Another says:—"The whole question will have to be gone over, and that during the coming season."

Another:—"I have been to shows from the South Coast to the far North of Scotland, and the Aquarium, which has the best produce, is the worst managed and most inartistically arranged of any that I have seen."

Yet another says:—"I greatly admire the bold position you have taken up."

Still another:—"The N.C.S. will do no good wherever its home is under its present management."

I could cite very much more; but the most encouraging congratulation, and the greatest compliment, is the unanimous resolve of the General Committee to ask me to reconsider the resignation I tendered as soon as I raised my pen as a protest against the conditions of affairs under which we are serving. The overwhelming majority of the General Committee

who are thus in favour of my cause, cannot, I think, act otherwise than towards a change of policy, which will have a beneficial effect on the future status of the National Chrysanthemum Society. I thank one and all for their sympathy, congratulations, and good fellowship.

One word more in conclusion. Are we not placing a severe tax on the many horticulturists who are more specially in the florist and decorative line by holding so many exhibitions? What benefit do they gain, say, by the December show? Mr. So-and-So only comes because another Mr. So-and-So will be there representing the special line: and so matters go on, not for these exhibitors' pecuniary benefit, or for the good of the N.C.S., but, as "A. D." puts it, "to exploit a glorified music hall." Is it not intolerable?—J. W. MOORMAN.

I will not weary your readers, nor occupy your valuable space, by reiterating all that has been said on the subject by your previous correspondents: I will merely content myself with saying that I should imagine there are very few members indeed of the N.C.S. who would not be glad to see the exhibitions and Floral Committee meetings held elsewhere than at the Royal Aquarium. The fearful crushing, shouting of rival showmen, the smoky atmosphere, the plethora of drink shops, excessive warmth, and the dreadfully bad light, are obstacles utterly opposed to the display, proper adjudication, or enjoyment of the exhibits.

The question is, Who is to blame for the Society continuing to hold its exhibitions at a place so utterly unsuited for the purpose? Well, I observe that some of your correspondents attribute the blame to the

FIG. 6.—CHRYSANTHEMUM EARLSWOOD BEAUTY.

THE N.C.S.—A FEW SUGGESTIONS FOR FUTURE ACTION.

I HAVE perused the correspondence in reference to the N.C.S. which has lately appeared in your columns with a considerable amount of interest. The discussion so far has been carried on in a perfectly fair and moderate tone, and I feel sure no one can deny that it has not been of a hopeful character. If your numerous correspondents who have taken part in the controversy have not been able to put forward any practicable and tangible scheme for providing new headquarters for the N.C.S.'s exhibitions they have, at any rate, shown that there are good grounds for ventilating the subject with a view to testing the opinions of the members as to the desirability of holding the exhibitions elsewhere than at the Royal Aquarium.

obstinaey and autoeracy of the Secretary: others to the lethargy of the Committee. According to my limited knowledge of societies and their powers, I am inclined to believe that the onus of responsibility rests more particularly upon the shoulders of the members. I hold that the duty of a secretary, be he honorary or paid, is to carry out the instructions of his committee in regard to all important details concerning the policy and general working of a society. It is not his duty to decide where the society shall hold its exhibitions, nor to "rush into print" and express opinions of an authoritative nature concerning the policy of the committee without its sanction.

It is the Committee's duty to formulate and carry out the general policy of the Society, whether it be the preparation of the schedule, the

admission of competitive classes outside the special scope of the Society's objects or within it, or deciding where and when the exhibitions shall be held; and if the Committee fail to discharge the duties devolving upon it to the satisfaction of the Society, the members have the opportunity of passing their judgment upon the matter at the annual meeting, and the power of electing to serve upon the Committee men who are pledged to carry out their duties in accordance with the views of those who elect them.

It is after all only natural that a committee, responsible for the government and finances of a society, should be cautious in undertaking any new departure that would involve pecuniary loss or prestige to it. But if the members exercised their rights of attending the annual meeting, and electing men on the Committee—men pledged to finding a new home for the N.C.S. exhibitions—the new Committee would be strengthened with the assurance that whatever they did in providing new headquarters would meet with the approval of the members; and if any loss occurred, no blame would be attached to them.

By all means then let every member who is opposed to the present policy of the executive attend at the annual meeting in February, and see if it is not possible to take active steps to put a stop to the present régime. It is of no use grumbling at the apathy of the present executive; better by far attend the annual meeting, and by voice and vote decide the question one way or the other.

It is not only in the matter of election of Committee, but also in that of Secretary, Chairman, Vice-Chairman, and other officials that the members should exercise their choice of selection. It is evident from the correspondence in your pages that the present Secretary is not a *persona grata* with a vast number of the members. Well, the latter have their remedy, though it be a drastic one. Let them come forward and elect a capable man, who will give his unqualified consent to carry out the instructions of the Committee; in fact, do what he is authorised to do and no more. Pay him a suitable salary, and let it be understood that he is the servant and not the master of the Committee, and of course has no vote at the board.

One correspondent has suggested that the son of the late Secretary (Mr. W. Holmes) would be a suitable person to fill the post. I beg to differ. With all due respect to this young gentleman, I say that it would be a serious mistake to appoint anyone connected with the trade to the post. Better by far go outside the trade and get an able man accustomed to book-keeping, recording minutes, and conducting correspondence, to fill the post, the same as in the case of the Gardeners' Royal Benevolent Institution. The exhibitions can be managed by a sub-committee, and as to the control of the finances, it would be better to place this in the hands of a competent sub-committee.

As to the Chairman and Vice-Chairman, good and worthy men only should be elected to these posts, men who show no aptitude for airing their own personal views and opinions and "leading the Committee by the nose," but who know the art of conducting the business of the Committee with absolute impartiality. Nothing whatever should be done by Chairman, Vice-Chairman, or Secretary, on behalf of the Society without first consulting the Committee.

There is, undoubtedly, too much of the "one man" element in the management of the N.C.S. at present; in fact this feature has been a predominant one in the management from the period when the Society was inaugurated as a "National" one. No society can hope to prosper for long, or give entire satisfaction, where such an objectionable feature exists.

Get rid of these anomalies, O ye "N.C.S.-ites," by exercising your prerogative rights, and then, and then only, will you achieve the goal of your ambition, see the Society once more on the high road to prosperity, its exhibitions held in a more appropriate place, and its prestige as the premier society of its kind in the world well and worthily upheld.—AN ON-LOOKER.

KINGSTON-ON-THAMES CHRYSANTHEMUM SOCIETY.

THIS once leading Southern Society seems to have fallen on evil days, and is just now beset with a series of troubles. It does not appear to have overcome the blow administered when Mr. George Woodgate left Coombe Warren for his more distant home, and the secretaryship fell into entirely amateur hands. Mr. Woodgate was so well known, had the full confidence of a large body of exhibitors, and the efficient assistance of a first-rate collector, hence in his time the annual exhibitions flourished.

Since then they have been gradually drooping. The present year's account will show a heavy balance to the bad. Then it is understood that the present estimable Secretary, Mr. Douet, is shortly leaving the neighbourhood, and now, not least, the Drill Hall authorities have resolved, after the end of March, to let the Hall no further in order to escape the heavy rates which burden them. For that reason the Chrysanthemum Society will, of necessity, have to seek another home if the shows are to be continued. Of late, too, it has been the practice too frequently to hold the annual show on the same day as the November show of the N.C.S. That has proved to be very detrimental, and unless in the ensuing autumn, wherever held, the show takes place during the week previous—that is, the first week in November—it had better be suspended altogether, which would be, of course, a grave misfortune.

Practically the only other place suitable for an exhibition locally is the fine Assembly Rooms at Surbiton, a far more desirable place undoubtedly, and much more conveniently situate than is the Drill Hall, but these rooms would be more expensive. Doubtless a general meeting of subscribers will soon be called to determine the course of action. It is high time that such course be made known.—A. D.

LADY LAWRENCE SPORT.

I HAVE a primrose sport on Lady Trevor Lawrence. Would someone kindly inform me if this is already in existence? Should this be *new*, I think it, like its parent, will become very popular, as *late varieties* of primrose colour are, I believe, scarce.—A. E.

CHRYSANTHEMUMS FOR INDIA.

I AM desired to send some Chrysanthemums to a gentleman in India. Can any reader of the Journal oblige by informing me—first, What kind of plant would best travel—the old stools shaken out, or young plants raised from cuttings? Second, How should they be packed to insure their arrival in good condition?—T. C.

CHRYSANTHEMUM MADAME CARNOT.

HAVING attended the N.C.S. Show last November, and admired the magnificent blooms of Madame Carnot, I was more than ever disappointed with my own. I grew two plants, and the buds were taken in August. A long bloom stem and a large bud on the top. Just under the bud smaller buds formed, as many as fourteen, hen and chickens fashion. I have spoken to several gardeners about it, and as many as nine told me that their plants came the same as mine, and they did not get a bloom at all, but the buds dwindled away. My object in writing this note is to ask if some of the practical readers of the *Journal of Horticulture* can tell me how this variety should be treated to avoid failure. Although I am not an exhibitor I like to have something good to invite my friends to see. It is very hard to labour at anything for nine months in the year in one's leisure time and get nothing in return. I feel certain that if we can be told how to successfully flower this fine variety many growers who have tried and failed will be thankful.—LOVER OF FLOWERS.

THE "BEST" VARIETIES.—WHO'S TO DECIDE?

"PLEASE send catalogue and mark the best twenty-four Japs" is a request I, and no doubt other trade growers, often receive. In a contemporary Mr. W. H. Lees gives a list of the best fifty, and a selection of twenty-four is again made from this number. Mr. Wells, on page 624, December 30th, of the *Journal*, favours us with his selection of the best sixty, from which again selections of the first twelve and twenty-four, and so on are made. To say which is the very best twelve or twenty-four is a task I have no wish to undertake, for some varieties do well one season and almost fail the next, while situation and method of culture, even among experts, have much to do with success or failure.

In the first twenty-four as given by both these experienced growers, we find Madame Carnot, Yellow Madame Carnot, Mrs. J. Lewis, Mutual Friend, Simplicity, Mrs. H. Weeks, Phœbus, Chas. Davis, Vivian Morel, Edith Tabor, Edwin Molyneux, Mons. Chenon de Leché; with this choice we all agree, except that some would perhaps prefer a little more colour; still, as twelve varieties, they are unequalled.

In the remainder of Mr. Lees' selection are Dorothy Seward, Miss Dorothy Shea, James Bidencope, Mrs. W. H. Lees, Modesto, Lady Byron, Col. Smith, Eva Knowles, Elsie Teichmann, Western King, Oceana, and Lady Ridgway. The first four of these last twelve Mr. Wells does not even place among his selection of sixty, which must be an oversight. Mrs. W. H. Lees is generally of a poor colour and form, but has size, and in spite of all that is written and said, size is the first consideration with most judges, and this variety is very frequently found in winning stands. Mr. Wells also places Miss Elsie Teichmann at the bottom of his list of sixty, which calls for comment, as most growers consider it one of the best yet introduced, while to omit Oceana, Lady Ridgway, and Modesto from the first twenty-four most persons will consider a mistake.

Those given by Mr. Wells, and omitted by Mr. Lees, are Georgina Pitcher, Julia Scaramanga, Australian Gold, Pride of Madford, Australia, Thos. Wilkins, Mons. Hoste, Mdle. Laurence Zédé, Lady Hanham, Madame G. Bruant, Madame Louis Remy, and Mons. Panckoucke. The first named, after a two-years trial with me, is undoubtedly good. The last but one is a white sport from Mrs. C. H. Payne, and is also being sent out as Lady Ellen Clarke, and may be considered a novelty.

Varieties that I should place among the first twenty-four are Sunstone, Mrs. Maling Grant, Master H. Tucker, Werther, Mrs. F. A. Bevan, and Ella Curtis, the first four of which are excluded from Mr. Wells' collection of sixty, whilst such varieties as International, Mrs. C. H. Payne, Madame M. Ricoud, and Amiral Avellan find a place therein. Strange to relate, Etoile de Lyon is missing both from Mr. Lees' fifty and Mr. Wells' sixty, and yet very few prize stands are without it.

In addition to those mentioned above, and not quoted by Mr. Wells, I prefer the following to many to be found in the list of sixty—Dr. Ziebert, Joseph Brooks, Geo. Seward, A. H. Wood, John Seward, V. Roger de Chezelles (tall, I admit, as are others recommended), Mrs. J. J. Glennen, Mrs. Chas. Keyser, Wilfred H. Godfrey, John Neville, Duke of Wellington, Madame J. Bernard; but stay! the "best sixty" is a much longer list than I thought, and to give a list of either the best twenty-four, thirty-six, or even sixty, is a task I will not set myself.

In conclusion, I would like to recommend Topaze Orientale as a true incurved. Mr. Molyneux omits this from his list on page 624. Of course he may not have grown or seen this, and he wisely mentions only those which come within this category. The variety is of easy culture, requires little dressing, is of fine form, delicate colour, and large in size. I am doubtful as to whether Madame Edmond Roger should be placed in this class any more than Louise, Robert Owen, and others now shown as Japs. Still another season will definitely settle this matter.—W. J. GODFREY, Exmouth.

SLUGS EATING WORMS.

THE enclosed very rough sketch, which I made in the kitchen garden, represents three slugs, "*Testacella Mangei*," eating a worm. You will observe one at each end of the worm, and the other tugging away at the middle of the unfortunate creature.

Whether these slugs do good or harm by destroying worms, I am content to leave to those who are competent to decide. They do not, however, confine themselves to worms, for I have frequently noticed them eating the mischievous black slug, and for this reason I never kill one of them, or allow the men to do so.

I do not know whether this is a common species. It abounds in our garden, and I believe it is responsible, to a large extent, for the small amount of harm done by slugs here.

I thought the above might possibly interest you. I notice various questions have from time to time been asked respecting this slug. I am not quite sure as to name I have given being correct, or of its correct spelling. I think, however, it is *Testacella*, but doubtful of *Mangei*. I have some recollection of the name of the above insect being in dispute some years ago.—THOMAS ARNOLD.

P.S.—I ought to say that I have never seen this slug eating vegetation of any kind, and believe it lives entirely on other insects. Is this so?

[The slug, *Testacella Mangei*, a native of South-west Europe, appears to have naturalised itself in some parts of this country. It is dark brown in colour, and the shell, at the extremity of the body, is larger than in the British species, *T. haliotidea*. This species occurs in many localities in the South of England, and has been found in Scotland. It is a dirty yellow, with brown specks, sometimes, but rarely, pale yellow, and even more rarely entirely black. The ear-shaped shell on the rear of the mollusc, and protecting it when in the burrow after worms, is about a quarter of an inch long, and the full-grown animal, when extended, about 3 inches in length. The carnivorous slugs do no harm, as whatever good worms effect in Nature they may be too abundant in cultivated land, especially the rich soil of gardens.]

CINERARIAS IN MIDWINTER.

CINERARIAS grown as annuals are extremely useful plants, and accommodating too. Although the regular flowering season is considered to be during the months of March and April, a good display may, with a little management, be obtained at midwinter and for a month before Christmas if desired, so amenable are the plants to different forms of treatment. A good number of plants flowering at the time named gives a pleasing variety after the bulk of the Chrysanthemums are past, the same plants lasting in good condition for a considerable time.

Apart from their usefulness as decorative plants, Cinerarias in a cut state are appreciated, the bright and varied colours appear so well under artificial light. No annual that I am acquainted with gives so much range in colouring as Cinerarias.

An advantage gained in flowering these plants at this time of the year is they are not nearly so liable to be infested with green fly as they are when flowering more at the ordinary season, when the weather is warmer. Where convenience exists, there is no reason why the plants should be in flower at one time. Whether it be during the middle of winter or in spring, a succession can easily be secured, provided space is available for a greater number of plants. The point to study is to sow the seed at intervals, instead of making but one sowing, as in the ordinary method of allowing the plants to flower as they will, say in March and April.

Some cultivators still adopt the old method of raising their stock of plants from offsets annually. Where special kinds or colours are desired no other method is so certain of success; but, nowadays, when such a wide range of colours as well as quality in the individual blooms can be obtained from seed through a reliable firm, it seems to me to be a waste of time to resort to the offset method. For flowering at Christmas, those raised from seed are better. Two sowings should be made—the first during the early part of May, and the second the first week in June. A succession of flowering plants is then assured, assuming, of course, neglect does not follow the initial stage. Any fine sandy, sweet soil will suffice to sow the seed in. Well drained pans are the best for the purpose, covering the pan with a square of glass. To maintain the soil in a moist state, a little moss over the glass will dispense with the necessity of shading the frame.

Directly the seedlings show through the soil remove the moss and tilt the glass a little to admit air to keep the plants sturdy. A weakly growth cannot produce dwarf plants with robust foliage and strong heads of bloom, such as are required to be effective in a decorative point of view, especially for house use. Plants ranging from 9 inches to double that size in height are best suited for decorative use at the time named. This is a point to be borne in mind.

The pots in which the plants are to flower should range from 4½ inches to 7 inches in diameter. These final sizes will guide the cultivator in giving the plants their preceding shifts. A compost largely consisting of leaves thoroughly decayed, with a small portion of loam and sand mixed with it, will be suitable in the initial stage; afterwards more loam should be added in the place of the leaves, with a small quantity of partly decayed horse droppings for the final shift. It is a mistake to allow the roots of Cinerarias to become matted together before they are repotted; the foliage becomes crippled, and the flower spikes are never so stiff as they ought to be.

Cinerarias must have abundance of water during active growth, and require frequent supplies of liquid manure, especially when the pots are small. Nothing is better than that made from cowdung and soot given in a weak state. Sulphate of ammonia at the rate of a quarter of an ounce to a gallon of water is beneficial after the flowering pots are well filled with roots. It imparts a deep green colour to the leaves, but it should not be given oftener than once a fortnight.

The first sowing may be made in a spent hotbed, the second in a cold frame behind a north wall. This latter affords the best site for all the plants for the first four months of their growth (including those sown in the hotbed after their first potting), as the trouble of shading the frames daily can be dispensed with, which will be a great saving of labour. Frames or pits with a southern aspect during the month of October will suit the plants better than their previous position, rendering them more compact in growth than they would be if remaining behind the wall longer. About the first week in November take them inside to a light airy position, as near the glass as possible. In our case we erect a temporary stage with boards across the border in the Peach house, which is kept as cool as possible; by that time the leaves have fallen from the Peach trees, the Cinerarias then obtaining plenty of light.

FIG. 7.—THE WORM-EATING SLUG.

There they remain until the flowering season is past. At no time of their existence must the plants be crowded, or they will certainly be spoilt. The leaves of one should only just touch those of its neighbour. Cinerarias suffer perhaps more than any kind of plant by overcrowding.

The plants are very subject to attacks of green fly, thrips, and the leaf-mining maggot. Frequent fumigations with tobacco will dispose of the two former pests when the first signs of the enemy are noted. For the latter hand-picking must be resorted to. The maggot can be seen in the leaves, and is easily removed with the point of a knife. Until the plants come into flower they are much benefited by syringings of clear water in the evening after a warm day.—E.

KITCHEN GARDEN NOTES.

WHETHER much work or little can be accomplished in the kitchen garden during January depends largely on the weather. On all favourable occasions it is desirable to proceed with digging, trenching, or bastard trenching. The best time for this work is cold, dry weather, or when the ground is clean and crisp with a slight frost. The worst time to tread upon or disturb soil is immediately after the breaking up of a hard frost or close upon the heels of heavy rain. More harm than good is done by working the ground when soil sticks to the boots and the tools.

Outdoor winter work requires careful planning beforehand. In the driest or frosty weather the heavy work of wheeling manure should be carried on so that the least damage is done to walks and edging. When the ground is too wet or sticky for profitably working pay attention to the rubbish heaps, stack leaves into compact heaps, turn and mix manure, separating from the heaps of decaying material anything that will not readily decompose, such as sticks, vegetable or herbaceous stems, hedge clippings, and prunings of all kinds. Make a fire with these and convert them slowly to ashes and charcoal by a process of subdued combustion. When the fire is well started pile on the whole of the combustible material and cover with weeds, wet leaves, or anything short and damp, which will tend to prevent rapid burning by shutting out the air.

This method of disposing of all useless waste which does not readily ferment is termed a "smother." The smother may be kept going for some time by closing up any apertures with damp material where the fire may break through. The result in the end will be a valuable heap of wood ashes and charcoal available for use in the preparation of seed beds and drills, and to fork in the surface soil before planting out Cabbage, Lettuce, Onions, Strawberries, and other crops.

The preparation of the manure for hotbeds is a matter which may also be attended to when the weather is unsuitable for other work. Stable litter and leaves are the best materials for forming hotbeds at this

early season. Strong and rapid, but a soon exhausted heat is not required. Horse manure ferments very rapidly, leaves less so, especially those of hard texture like Oak and Beech leaves. These are the best to obtain and mix with manure in equal parts for early hotbeds covered with or placed in frames. The surface of the bed then covered with about 9 inches of soil, early crops of Radishes, Lettuce, Horn Carrots, and kidney Potatoes may be secured.

Some gardens possess a favourably situated border facing south, and protected with a wall, which not only prevents winds and storms sweeping along to some extent, but radiates heat from its face. Should the soil also be light, fertile, and well drained, as it usually is on such aspects, the ground ought, on the first favourable opportunity, to be prepared for sowing early crops of Peas, Beans, Spinach, Lettuces, and Radishes, and the planting of early kidney or round Potatoes.

Hoeing between any growing crop, such as Cabbage, Winter Spinach, or autumn-sown Onions, whenever the soil becomes dry enough on the surface, will promote nitrification and consequently encourage growth.—E. D. S.

NOTES ON FIGS.

In establishments where Figs are grown and highly appreciated, it behoves those in charge of the trees to give them close attention from the present time and onwards. We have a comparatively large collection, and have to maintain a supply over as long a period as possible, and it has occurred to me that a few notes on seasonable points will be acceptable to many readers.

EARLIEST FORCED TREES IN POTS.

The terminal buds having started, advantage should be taken of the mild weather that may prevail to increase the temperature of the house, as when Figs are fairly started into growth they delight in a good heat, plenty of moisture, and all the light that can possibly be given to them; the glass therefore must be kept clean and air admitted, so as to prevent it being constantly covered with moisture. Maintain a night temperature of 55° to 60°, ventilate a little at 70°, losing no opportunity of admitting a little air when the morning promises an increase from gleams of sun, and close sufficiently early for the temperature to rise to 80° or more.

Syringe the trees and walls twice a day on fine days, but when the weather is dull and wet omit the afternoon syringing, and damp the floors in the evening instead, as the trees are weakened and the foliage made soft by keeping them wet during the night. Be careful not to allow the heat about the pots to exceed 70° to 75°, and if the materials are heating too violently turn them as a means of reducing the bottom heat, but it ought to be kept steady. Trees started now, and with bottom heat, will give fruit in May. The varieties we find best for pots are small-fruited—Early Violet and St. John's; large-fruited—Pingo de Mel and Brown Turkey.

EARLY HOUSE OF PLANTED-OUT TREES.

The best all-round Fig is Brown Turkey, as it gives good results both in the first and second crops, the former ripening early in June, and the latter in August and September. Maintain a night temperature of 50°, 55° by day, and 60° to 65° from sun heat. Trees that have been started about the same time for a number of years push growths with little excitement; but young ones that have not been forced start tardily, and are often given more heat in the early stages than is good for the crop. This should be avoided by bringing the trees on slowly, seeking advancement by sun heat more than artificial in dull weather. Apply water to the border not colder than the mean of the house, bringing the soil into a thoroughly moist condition. Syringe twice a day with tepid water, a little warmer than the house; but in dull weather damp the paths, walls, &c., only, syringing always sufficiently early to allow the trees to become dry or nearly so before dusk.

SUCCESSION HOUSES.

Proceed with pruning as convenient, thinning the wood where crowded, cutting back that which has reached the extremity of the trellis to growths well disposed for supplanting the branches cut away in bearing. Thoroughly cleanse the house, and limewash the walls. Wash the trees with warm soapy water, using a brush, and the trees having been infested with scale or red spider use a softsoap solution, 4 ozs. to a gallon of water, and a wineglassful of petroleum. The softsoap must be dissolved by boiling in a quart of the water, the petroleum added whilst boiling hot, but the vessel removed from the fire, switching well to form an emulsion, and then dilute to 1 gallon, or add the 3 quarts of water remaining hot, and use at 130° to 140°. It is necessary to dislodge the scale, effecting that by using a half-worn painter's sash tool, thoroughly cleansed from paint. Remove the loose surface soil or mulching, and supply fresh lumpy loam with a sprinkling of steamed bonemeal, three parts; sulphate of potash, two parts; and ground coprolites, one part, mixed, a good handful per square yard, and scratch in with a fork. Keep the house as cool and dry as possible, merely excluding frost, or not allowing the temperature to fall many degrees below freezing point.

YOUNG TREES IN POTS.

Where these are wanted for early work another season they should be placed in gentle heat during this month, in order that they may make and properly ripen their growths by September. They must be potted without delay, using good rather strong turfy loam, with a fourth of old mortar rubbish, and a fifth of thoroughly decomposed cow

manure, draining efficiently, and potting firmly. Train them with a single stem, and allow the branches to radiate so as to form a good bush or pyramid. Insert cuttings or eyes of any varieties it may be desirable to increase, and in order to make a good growth they should be encouraged with bottom heat, and started not later than the beginning of February.—GROWER.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—JANUARY 11TH.

THE exhibition on the above date was the first of the year 1898, and was, all things considered, a capital one. The exhibits were not very numerous, but were of conspicuously good quality, and fairly well diversified. Cyclamens and Primulas made very pleasing displays, and were somewhat largely shown. Orchids with fruit and vegetables were not very numerous.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with Messrs. G. Bunyard, J. Cheal, A. F. Barron, T. J. Saltmarsh, A. Dean, W. Bates, W. Farr, C. Herrin, W. J. Empson, G. Wythes, H. Balderson, F. Q. Lane, G. Norman, J. Willard, R. Fife, and J. H. Veitch.

Mr. W. J. Empson, gardener to Mrs. Wingfield, Amptill House, Amptill, staged a collection of thirty dishes of Apples, for which a silver Knightian medal was awarded. The varieties were well coloured, and all the fruits were in an excellent state. Mr. J. Bury, Petersham Vineries, Byfleet, sent a splendid collection of Grapes as grown and packed for market. The bunches were in cross-handled baskets, and could not take harm in travelling. A silver Knightian medal was awarded. Mr. J. Miller, Ruxley Lodge, sent a box of fine Mushrooms, and Messrs. Rivers & Son, Grape Directeur Tisserand and some Citrons.

Prizes for Flavour.—The first prize for a dish of Pears went to Josephine de Malines, staged by Mr. C. Ross of Welford Park. The first for Apples was taken by Mr. J. Tallack for Margil, and the second to Claygate Pearmain from Col. Brymer.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Laing, H. B. May, R. Dean, C. T. Druery, J. H. Fitt, J. F. McLeod, J. Hudson, J. T. Bennett Poë, J. Walker, J. D. Pawle, C. E. Pearson, C. E. Shea, G. Gordon, E. Beckett, C. Blick, H. Turner, G. Paul, and J. Fraser.

Cyclamens and Primulas made a very rich display in the Drill Hall, and were contributed by several different firms who make a speciality of this most useful of winter flowers. Messrs. H. Low & Co., Upper Clapton, sent a number of Cyclamens of the grandiflorum section. The plants were in 6-inch pots, and were producing flowers of good size and varied colours. From the same firm also came plants of Carnation Winter Scarlet, of which the flowers were very bright in colour, and of good form (silver Banksian medal). Mr. J. R. Box, Croydon, exhibited a handsome stand of Primula sinensis, comprised of plants that had been splendidly grown. Amongst the varieties noticed were Princess Mary, Surprise, Wickham Beauty, Firefly, Queen, Rosamund, Wickham White, White Perfection, Emperor, Cannell's Pink, Marquis of Lorne, Margaret, and Mrs. Pereira (silver Flora medal).

The whole of one side of a long table was occupied by plants of the celebrated Swanley strain of Chinese Primulas. The plants were small but very healthy, and the flowers they were carrying particularly rich in colour. Many of the several varieties staged represented forms raised by Messrs. H. Cannell & Sons, and a few of the most conspicuous were Eynsford Red, Cannell's Pink, Distinction, Emperor Improved, Eynsford White, Swanley Blue, White Perfection, Kentish Purple, Victory, My Favourite, and Pink Queen of the singles, with Feronia, Earl Beaconsfield, Annie Hillier, King of Purples, Mrs. R. Crabbe, and Marchioness of Exeter of the doubles (silver Flora medal).

The large exhibit of Cyclamens from Messrs. Sutton & Sons, Reading, was one of the most charming in the show. Every one of the plants staged bore the impress of fine quality and the best of cultivation. It would have been a matter of impossibility to find a really bad plant, and no better criterion of the excellence of the Reading strains than this collection. The plants, all in small pots, were carrying beautifully marbled foliage, and flowers of singular purity of colours in the utmost profusion. There were pure white, rose, salmon pink, purple, crimson, and several other colours, representing such varieties as Salmon Queen (silver Flora medal).

Messrs. J. Veitch & Sons, Ltd., Chelsea, staged baskets of Hamamelis arborea, H. japonica Zuccariniana, and Garrya elliptica, with a box of flowers of hybrid Rhododendrons of charming colours. The only exhibit of miscellaneous flowering and foliage plants was contributed by Messrs. J. Laing & Sons, Forest Hill. There were Crotons, Palms, Dracenas, Begonia Gloire de Lorraine, Cyclamens, Nepenthes, Poinsettias, and others (silver Flora medal). Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, sent pans of Narcissus monophyllus, composed of well-flowered plants.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, de B. Crawshaw, H. Ballantine, W. H. Young, H. Little, H. J. Chapman, T. Statter, T. W. Bond, E. Hill, J. Douglas, and S. Courtauld.

Orchids were very sparsely shown; in fact, there were only two exhibits of any size, and even these were not very large. Messrs. F. Sander & Co., St. Albans, showed a number of plants, conspicuous amongst which were Lælia anceps Sanderiana, L. a. Hilli, L. a. Dawsoni,

Dendrobium Johnsoniæ, D. Dulce, Oakwood variety, *Lycaste Skinneri*, with a few *Cypripediums*. Messrs. H. Low & Co., Clapton, sent a small group, of which *Odontoglossum Andersonianum*, *O. crispum*, *O. c. Tackianum*, *Cypripediums Clotho*, *Bellona*, F. S. Roberts, and *Lathamianum* were the best. Mr. A. Chapman, gardener to Captain Holford, Tetbury, sent a group of cut Orchids, amongst which were several of good quality, and received a silver Banksian medal.

AWARDS OF MERIT.

Cattleya Trianæ Sanderæ (F. Sander & Co.).—A very pleasing form of the type. The sepals and petals are very delicate blush, the latter being broad and slightly fimbriated. The shapely lip is rich crimson, with a suffusion of purple and a yellow throat (award of merit).

Cypripedium F. S. Roberts (H. Low & Co.).—This is a very charming form. The ground colour is white over the whole, the spots being claret in colour and very numerous. The pouch has a patch of this shade (award of merit).

Lælia anceps Amesiana Crawshay's variety (de Barri Crawshay).—This is a lovely form. The broad petals, almost white at the base, deepen in colour until at the tip they are bright red. The colour of the lip, which is rather small, is peculiarly deep velvety crimson (award of merit).

LONICERA SEMPERVIRENS.

IN supposing this plant to be quite new M. J. Davis is in error, for it has long been known and grown for twining up the rafters of a cool greenhouse. For this purpose few plants are better suited than this lovely North American Honeysuckle. The terminal clusters of trumpet-shaped flowers (fig. 8), which are produced during spring and early summer, hang down in great profusion, and are very showy, being brilliant orange-scarlet with yellow inside the flowers, and contrast well with the glaucous green leaves. If planted out of doors in a warm and sunny situation it flowers freely during the summer, but, unlike most of our hardy Honeysuckles, it has no scent. There is another variety of this delightful species called *L. sempervirens minor*, which is also useful for a similar purpose.

NOTES ON PRIMULAS.

THERE are few small indoor flowering plants so generally useful as the Chinese Primrose. It has been in this country now some fifty years, but it is within the last twelve or fifteen years that the greatest advance has been made in raising improved varieties. The double sorts are very valuable, especially for cutting, as they last much longer than the single varieties. For bouquets they are also most useful. As decorative plants, however, the single varieties are in the greatest demand, and are the most serviceable. The Primula is easy to grow, provided it receives fair treatment and its requirements are studied. A light position is all-important. In the winter the plants cannot be too near the glass, and at that season they require a little more heat than an ordinary greenhouse, otherwise, as most growers can testify, they are liable to damp off at the collar.

The usual method is to raise fresh plants every year, destroying the old plants as soon as they have flowered or have ripened seed, except in the case of any that may appear to possess some superior quality. To have them strong for flowering towards the close of the year, the first sowing should be made at the beginning of March. Well-matured plants that have not been pushed on too quickly are not so likely to damp off as those which have been hurried. The seeds of Primulas require care in sowing, or they will not germinate. In all stages Primulas cannot endure any approach to stagnation in the soil, consequently the pans must be well drained, placing a layer of dry manure over the crocks. The soil should consist of three parts good loam sifted, and two parts sand and decayed leaf soil in equal proportions (the latter sifted). The whole being well mixed together, fill the pans with this compost to within an inch of the rim, and press it down moderately firm. Sprinkle a little sand and press the surface smooth, next give a gentle watering to settle the soil; then sow the seeds evenly, and scatter some very fine compost half soil and half sand over them to the depth of about the eighth of an inch; again smooth the surface by gentle pressing, then cover with brown paper, which will keep it damp, so as to obviate the necessity for giving water until the plants appear. Care must be taken that the paper does not remain on longer, or it would cause them to become drawn. After they have advanced a little place them in a light situation, shade them with any light material which will protect them from scorching without darkening them too much. Give a little water as they require it, and when large enough prick them out $1\frac{1}{2}$ inch apart in pans of soil similar to that in which the seed was sown.

When they have leaves nearly an inch in length they must be placed singly in 60-size pots, employing the compost before mentioned. After potting, the best place for them will be a shelf in a light house or pit in an open situation. Place the plants close to the glass. This is of importance, as if in the bottom of a pit or house and near together their leaves become drawn, and the plants not only have a weak appearance, but also will not produce half the quantity of flowers they will do if strong and vigorous. When the weather is very bright they should be

slightly shaded, ventilating freely during the day, and at night when mild. As soon as they have filled their pots with roots they may be transferred to 6 or 7-inch pots, which, for all ordinary purposes, are large enough to grow and flower them in. The soil this time must consist of three parts good loam broken with the hand, one part of leaf soil; add a little bone dust, and as much sand as will keep the whole porous. Pot firmly, and leave sufficient room for watering. The best position for them until September is houses or pits as already advised, up to which time the flowers they from time to time produce should be removed, unless early blooming is required. To keep the atmosphere free from damp employ fire heat occasionally, and if a little warmth is kept on so as to have the night temperature at 45° the flowers will be much larger,

FIG. 8.—LONICERA SEMPERVIRENS.

and produced through the winter in greater quantities. As the flowers are being produced give liquid manure freely, as it will be of great assistance to them.

The double and semi-double forms of this flower are increased from seeds sown and managed as described in the case of the single varieties, also by cuttings made by a division of the crowns with a portion of stem attached. These root best in small pots in sandy soil in a moderate heat. They must not be in a very humid atmosphere—only sufficient to keep them from flagging, or they are liable to damp. When they are well rooted transfer them to 4-inch pots, employing soil similar in every way to that advised for the single kinds. Pot them low, so as not to leave any of their stem bare. So treated they will thrive much better than with the common practice of leaving a considerable space between the soil and the bottom leaves. Through the summer let their treatment be the same as that of the single sorts, but in the winter they do far the best when kept in an intermediate temperature of 45° or 50° at night, and a little higher in the daytime, with ventilation when the weather is suitable.—M. T.

THE MANURIAL VALUE OF SOLUBLE PHENYLE.

IN reply to Mr. Abbey's bold challenge, I offer the following facts in support of my statements:—

1, *Composition of "Soluble Phenyle."*—On consulting your columns a few weeks back, I came upon a "tit-bit," which is duly installed in my album of chemical curiosities. A meek inquirer was bantered for confounding "phenol (C_6H_5O)" with "soluble phenyle, which was C_6H_5 ." I challenge Mr. Abbey to explain the manurial value of C_6H_5 , and further offer him a copy of a recent text-book on organic chemistry if he can provide me with such a substance as C_6H_5 . Although apparently a homely and familiar article to your respected contributor, it seems to be quite an unknown monstrosity to chemists. The only excuse I can give for stating the composition of "soluble phenyle" in the form I did is that it presented the inventor's own statement of composition as set forth in his patent specification. How about C_6H_5 now?

2, *Potash in "Soluble Phenyle."*—The sole source of potash in the scheduled mixture is the softsoap. The 1 per cent. of potash is due to this material alone. As an agricultural chemist I should assess the manurial value of "soluble phenyle" at 4s. per ton at current prices for potash.

3, *The Nitrogen in Soluble Phenyle.*—"Creosote" I do not know, but if creosote be meant, then I state that the nitrogen in creosote is not in the form of salts of ammonia, or of any substances which yield ammonia or nitrates in the soil. I have just tested a sample in my laboratory. The nitrogenous substances are stable basic bodies such as pyridin— C_5H_5N —and are extremely poisonous not only to plants, but to bacteria and other soil organisms. Soda is quite without effect on these bodies. No ammonia is evolved on boiling creosote with strong caustic soda solution. I have known Hops killed through contact of the roots with a recently dipped pole.

4, *The German Government* has been spending £20,000 a year in attempting to cure the eelworm disease of the Sugar Beet. They would doubtless be grateful to Mr. Abbey for suggestions and information.

5, *Kainit.*—This is known to be highly injurious to many plants, especially when grown in restricted soil, and gardeners should not be surprised to find the kainit sometimes worse than the disease.

6, *A Practical Proposal.*—Quite apart from the eelworm, we have most divergent statements recorded as to the manurial effects of "soluble phenyle." Why let the matter rest? I propose that several of your readers who are interested in the matter should conduct the following test in combination:—

Select six healthy Cyclamens or other pot plants and set them aside for experimental (and, perhaps, sacrificial) purposes, and treat as follows:—Plant 1, normal treatment with water only; plant 2, watered freely with Little's soluble phenyle, 1 oz. in 1 gallon of water; plant 3, do., 1 oz. in $1\frac{1}{2}$ gallon; plant 4, do., 1 oz. in 6 gallons; plant 5, watered with kainit, 1 oz. in 1 gallon of water; plant 6, do., 12 ozs. per gallon. The results should be duly reported in this Journal.—HALOGEN.

[We believe Mr. Iggulden's settled practice with phenyle, as recorded on page 16, was based on careful experiments. He is not the man to act recklessly, and thus risk injury to his plants and crops. At the same time, the experiments suggested are well worth trying. If Mr. Abbey accepts the challenge which he has invited he will do so the more effectively by doing it as briefly as possible, or by acting on his own advice to "let the answer be clear," and supported, if not by practice, by chemical authorities. We want no more bantering by either one side or the other.]

LILIUM SPECIOSUM.

It is not very generally known that the period at which *Lilium speciosum* may be had in bloom can be very greatly lengthened, and this simply by the time at which different bulbs are started, the first quantity being by a very gentle system of forcing hastened into flower about the middle of July.

Where fine specimens are wanted choose 12-inch pots, giving them efficient drainage. For soil use an admixture of good turfy yellow loam partially decomposed. I prefer that in which abundance of white sandy grit is found. This should be chopped up into moderate-sized lumps, to be afterwards sifted to remove all the more dusty portions of the soil. The more turfy portions only ought to be used. With this mix a few lumps of charcoal, some well-decomposed leaf mould, adding a dash of silver sand. Fill the pots to within 3 inches of the top with these well mixed together, making the whole tolerably firm. Into this firmly press the bulbs, taking care not to bruise or otherwise injure the scales. Let the tips of the upper scales upon the bulb appear through the soil, placing the same firmly around them. This is very essential to all fresh-planted bulbs. The number I generally place in a pot of the above size is from seven to nine. It depends whether any of them are likely to produce two stems upon the single bulb.

Any who may not wish to have large specimen pots, or may prefer to have them of a more portable size, cannot do better than choose 7-inch pots, in which four or five bulbs may be placed in a similar manner. These smaller pots will not need half the care and attention that the larger ones do, as the same caution as to watering need not be observed. The large mass at this early season of the year getting so easily overlaid with moisture, will cause the soil, being without roots, to sour if great care is not observed.

Place the pots in a situation where they will receive a moderate amount

of light and heat; the temperature not to be below that generally kept up in a greenhouse. As I have before observed, care should be taken, especially at this early season, in watering them. They will require none until the plants have made a start, when a thorough soaking of tepid water will greatly benefit them. They should now be removed into a temperature of at least 55, with light and air. When they have made a growth of 6 or 7 inches they can be removed to the more airy end of the greenhouse, or to a pit, from which the frost is excluded.

At the base of that portion of the growth which may be above the soil, a quantity of strong healthy roots may be observed; firmly cover these with some pieces of turfy loam and leaf mould, sufficient to fill up the pot to within the customary distance from the rim. With occasional sprinklings, and as they advance in growth more liberal root-waterings, they may, taking care to tie them when necessary, remain in this situation until the period of their flowering, which from a January potting should be about the middle of July at the latest.

The next set may be potted about the middle, or at the end, of February. These should be treated precisely like the former, save that they will require no heat, but should be placed in any sheltered position until they show signs of growth, when they should be removed into a light, airy situation, where the frost cannot reach them, there to remain until they require staking, and are showing for flower, which will be about the end of August.

The next in succession are to be grown entirely in the open ground, where they will flower readily with the following simple treatment. Pick carefully out of the old soil every bulb. I dibble these out in the ground where they are to stand, four or five in a patch, taking care to place them some 5 or 6 inches deep. I find a bed very suitable for them which is composed of an admixture of heavy sandy loam and peat. These small bulbs, some of them scarcely more than a scale in size, perfect a growth sufficient in one season to flower in the following one, and thus I have annually in that spot a goodly bunch of these blooming more or less efficiently according to the season, and giving a succession of flowers from July until the frosts of autumn visit us.

These Lilies have the additional merit of being good flowers for travelling long distances without losing either beauty or fragrance. They should be taken off the main stalk with a reasonable quantity of the flower stalk, at from two to four days before the period at which they would naturally expand, and if desired to be sent any distance before expanding, they only require to be placed where they will not become crushed, wrapped up in paper.—E.

NOTES ON PEARS.

THE contributions on this important fruit are most instructive. Cannot we be favoured with more notes from practical men on this and kindred subjects? They would, I think, meet with general acceptance by gardeners.

"W. S." (page 621) has not much faith in Glou Morceau Pear this year. With me it is very indifferent in flavour, though in other years it has been much more juicy and agreeable. I fancy it requires a warmer room to develop its flavour. Bergamotte Espere is now ripe with me, but is only of very moderate flavour. The tree is a prodigious bearer, and is on a wall in a south-west corner. Jean de Witte, a little known variety, a medium sized russety Pear, something after Winter Nelis, is just over. The tree is an espalier, and for the first time in four years has been in good condition.

Madame Millet, a Pear of good appearance, not unlike the foregoing, is still hard, and refuses to approach ripeness; it stews very well, and that process appears to be its destiny. The same may be said of Bcurré Rance, which I see is mentioned in Mr. Bunyard's catalogue as "one of the best late Pears." I have never yet had the pleasure of tasting a fruit in perfection, and should be glad to know how to get it into that state of ripeness, which hitherto I have failed to do.

Easter Beurré is not what I can call a pleasantly flavoured Pear; it is always more or less gritty, and with me scabby. When good and clean the fruit is handsome, and tells on a dinner table, but in appearance only. I know, with "W. S.," of no really good Pears after Winter Nelis is over. It would be a boon if some horticulturist could improve the size and at the same time retain the flavour of this excellent Pear.

Coming to an earlier season, Beurré Superfin vies with Marie Louise as hard to beat; though not so sweet as the last named, it is most refreshing and juicy, and a good bearer. I have it on a west wall. Were I to be asked to name the Pear *par excellence*, I should be inclined to choose Doyenné du Comice. I have several trees on an east wall, and although the variety is not a consistent cropper with me, the fruit is of extra size, beautifully coloured, and of superb quality. Well may one urge those not possessing this variety to lose no time in finding room for one or two trees without delay.

Tomtits are not slow in recognising the most toothsome varieties, and they play sad havoc with this Pear. Is there no more approved way of dealing with these destructive little creatures than by putting slit cardboard over each fruit (a tedious business), or netting the trees? I am afraid the planting of Sunflowers near the Pear wall has but little effect, and does not seem to act as a deterrent against the birds taking just one peck at the base of the fruit, which eventually means decay at that point.

Referring to fickle varieties, I may mention Hacon's Incomparable, Ne Plus Meuris, and Beurré Bosc. Not one of these is satisfactory in ripening the fruit. The first and last named are on a west wall, open to the north. Perhaps this position is too cold for them. Ne Plus Meuris is on espaliers, and is always very loth to ripen. Maréchal de Cour and Van

Mons Léon le Clerc are sure bearers. The former is the better flavoured, and both are good doers. Dr. Trouseau has a peculiar flavour, and is only appreciated by a few, but is, nevertheless, a fine November Pear of extra size.

Where one has to supply the wants of the younger branches of a family with fruit, the Seekle comes as a general favourite. This sweet, musky, delicious Pear never goes begging. Beurré Bachelier is a large green, uncut Pear, of only moderate quality; it is a good show fruit, and a strong grower. The Crassane Pear is easily recognised by its long stalk; it generally bears at the extremities of the branches, and is not a heavy cropper, but has an agreeable flavour. In my case it was planted on a north wall, which, I take it, is much too cold a situation. I have given a brief list, and shall be glad to note other articles dealing with the merits or demerits of this indispensable fruit—the Pear—in other quarters.—GEO. DYKE, *Stubton Gardens, Newark.*

EELWORM DESTRUCTION AND CONTROVERSY.

I THINK the last twelve words of your footnote to Mr. Abbey's article on "Eelworm Destruction" (page 16) would meet with the approval of many subscribers to your Journal. Perhaps these good men who write so airily in your columns, and quote certain cures one week, and the next state that the cure before mentioned is worse than the disease, little think what anxiety they cause to small growers of Tomatoes and Cucumbers like myself, to whom the loss of plants by eelworm or otherwise is a loss indeed. Besides, of what use or interest is it to your readers to watch Mr. Dyke and Mr. Abbey, or anyone else, writing caustic remarks anent one another's experience?

Reading Mr. Dyke's short article *re* the application of kainit and basic slag, I came to the conclusion that advice from such a practical source must be right, and applied the manures as advised to my borders. Now this week I understand from Mr. Abbey that I have probably poisoned my borders.

Who is right and who is wrong? "Less bantering and boasting." Just so. A little less of that and more precise and clear information would be more appreciated by the subscribers to your excellent Journal, from whose pages I have culled many a wrinkle and spent many happy hours in reading. Now, Messrs. Dyke, Abbey, and Iggulden, a plain answer to a plain question: Is it safe to plant Tomatoes and Cucumbers in my borders as prepared? I trust you will find room for this.—W. B.

[We are pleased to find room for matter which imparts or elicits definite information as well as for that which entertains and enables pleasant moments—in the aggregate "happy hours"—to be "spent in reading," but we do not invite communications in which the main object of a writer appears to be the tripping-up of another whom he likes to regard as an "opponent," and airing his own superiority. There should be no opponents in the worst sense of that term, but coadjutors who respect each other, while in different ways seeking for truth in the interests of all. At the same time many readers like occasional relief from stern work, as the following postcard indicates:—

"Plain solid beef and pudding are most excellent in their way, but occasionally the stomach craves lighter food. This applies equally well to the mind, and we, the readers of the Journal, owe 'Ess and I' a debt of thanks for calling forth that piece of light reading in last week's issue. How 'Ess and I' may like it is another question, possibly they are quite glad to be pilloried for the general benefit. 'All work and no play makes Jack (and his missus) dull.'"

Reverting to the slag and kainit mixture, obviously Mr. Dyke gave a record of practice and its results on page 547, December 9th, but at the same time clearly stated the dressing was given long prior to the planting of the Tomatoes, for, he says the soil was "again forked over in February." Mr. Dyke stated that 2 lbs. of basic slag and 12 ozs. kainit per square yard were well blended through the soil by twice forking it over. Mr. Abbey, on page 16, January 6th, says, that after several years' experiments "1 oz. of kainit and 3 ozs. of lime may be used per square yard, to each one inch depth of rich vegetable, worked, or prepared soil." Suppose the depth of soil is 12 inches, where is the difference between the dressings of the two advisers? The amounts of kainit would then be the same in both cases, while there would be a decided excess of lime in Mr. Abbey's dressing over that in the slag of Mr. Dyke, while the phosphates in this would be beneficial.

If Mr. Abbey said (as we do not think he did) that such a dressing would poison the borders they would be poisoned by his own advice. He has, perhaps, confused you by a curious reference to "12 ozs. of kainit to a gallon of water," as if Mr. Dyke had advised the solution, which we do not remember seeing, and if he did not, though he has made no complaint on the subject, we are sorry the reference appeared on the page last cited.]

HAREWOOD HOUSE GARDENS.

DURING a few days in the county of broad acres I paid a visit to Harewood, one of the stateliest of homes in a county of historic houses. As a brief outline of the exterior splendour of this seat of the Earl of Harewood was given in the *Journal of Horticulture* on the 22nd of July, 1897, my remarks will touch only on a few salient features in the houses. No one expects to find a gorgeous display of bloom or a wealth of luscious fruit in the dark and waning months of the year.

A series of large house parties had been given for the shooting season,

and this means an absorption of fruit, flowers, and vegetables. The first house I entered was one kept principally as a flowering house, about 60 feet long, and of proportionate width and height. The back wall Mr. Jeffrey has planted with an assortment of old-fashioned climbing plants too rarely seen, amongst which were observed *Swainsonia alba*; *Lasiandra maerantha*, displaying its intense purple blooms; *Luculia gratissima*, clothed with its fragrant clusters of delicate mauve flowers. *Habrothamnus elegans* was also in flower, and *Lophospermum scandens* was luxuriating on this wall in company with the peppermint-scented *Pelargonium* and Ivy-leaved varieties. Up the rafters were *Bougainvillea glabra* and *Clianthus puniceus*, whilst in the centre of the house was an arched bower of *Maréchal Niel* Roses. These climbers are all thinly and regularly trained, and no plants are allowed tall enough to obstruct the light in front of them. This is evidently the secret of their floriferousness as seen at Harewood. The centre bed of this house was enlivened with *Camellias* in flower, *Oranges* in fruit, *Chrysanthemums*, and *Indian Azaleas*, the front of the brickwork being luxuriantly draped by *Tradescantia zebrina*, often seen in a higher temperature than an ordinary conservatory, and less pleasing than here. The front stage was gay with *Chinese Primulas*, *Zonal Pelargoniums*, *Paper-white Narcissus*, and *Linum trigynum*.

The next two plant houses—stoves—have been entirely reroofed and fitted with modern ventilators since my last visit. They were mostly filled with ornamental foliage plants and climbers on the roof. *Ipomæa Horsfieldi* was displaying its charming blooms, and several plants of *Strelitzia Reginae* were opening their gorgeous flowers, and it was interesting to learn from Mr. Jeffrey that these have great endurance when cut. One forcing house was occupied with *Asparagus* and *French Beans*, another with winter Cucumbers in bearing, and also *French Beans*.

Orchids, of which there is a small collection, looked healthy. *Bouvardias*, *Calla æthiopica*, *Double White Primulas*, *Zonal Pelargoniums*, *Clivias*, *Freesias*, and *Lachenalias* were all in good health; whilst bulbs in variety, with *Lilae Charles X.*, *Azalea mollis*, and *Violets* were present to supply the wants of a great house.

In the exotic fernery the collection numbered by dozens of large plants of *Adiantum farleyense* and *Cheilanthes elegans* were most remarkable. The former, with large broad fronds, are mostly in 8-inch pots. These plants have all been grown from single crowns, which is one of the secrets of successful culture. As this house faces due south great care is exercised in shading. Recently two of these large *A. farleyense* were used on the dinner table, set in vases of gold.

Among Grapes the large old Canon Hall Muscat had still about fifty bunches hanging of a golden amber tint, and consequently perfect in finish. *Gros Colman* was also in another house, faultless in size and colour. The late house had over 100 bunches of *Lady Downe's* and *Black Alicante*, perfect in every respect. A rod of Mrs. Pince's *Black Muscat* in this vinery was almost faultless in finish. The Peaches in the four houses had made clean and well-ripened growth, bristling with fruit buds. *Royal George* is a great favourite here, and a tree or two of this variety is grown in each house. Many large Palms are required for room decoration, and in one house were some good examples of *Kentia Fosteriana*, *K. Belmoreana*, *Phoenix tenuis*, and *Chamærops Fortunei*.—F. STREET.

THE YOUNG GARDENERS' DOMAIN.

ONION CULTURE.

THE Onion requires a deep rich rooting medium, therefore the soil must be well trenched and manured. The best soil for general purposes is one of a deep sandy nature: but for exhibition, better results are obtained in a strong black or red loam, in an open situation. Prepare the ground in October by a trenching three spits deep, at the same time working in plenty of good farmyard manure, the shortest and most decomposed being placed near the surface. Leave the surface rough, so that it will be exposed to frosts. In January it should receive a heavy top-dressing of soot and lime, this being forked in during March.

For general purposes, the third week in the latter month is early enough for seed sowing, when, in the case of light soils, the surface should be raked level, and rolled or trodden firm. Sow the seeds in drills 6 or 7 inches apart, and if procured from a reliable firm, sow thinly, and leave all the plants to grow. As soon as they are 2 or 3 inches high, hoe them carefully, and about every fortnight afterwards as long as they continue to grow. Keep free from weeds, and in dry seasons they will be greatly helped by liberal supplies of water and a mulching of short manure.

As soon as the tops show signs of ripening pull them up by hand, and lay two rows facing each other, the roots being uppermost to get plenty of sun and air. If the weather is fine turn them at intervals of two or three days, so that every part will become properly ripened. In the event of showery weather they may be better harvested if empty cold frames are at hand, laying them out thinly, turning them as previously advised, and giving them plenty of air. When well finished the loose scales and tops should be removed from them, sorting out the picklers and diseased ones as the cleaning proceeds. Store them in cool airy sheds free from frost, or in a room kept specially for them.

For exhibition the ground should receive the same treatment, and the seeds be sown in boxes in February placed in a cool vinery or frame. When the young plants are an inch or two high prick them off into other boxes of light soil 2 or 3 inches apart, growing them in gentle heat, and gradually hardening before planting 10 inches apart each way. When growing freely liberal supplies of liquid or artificial manure are beneficial, also hoeing and mulching as before.

stated. Wood ashes or burnt earth is said to prevent or check the maggot to a great extent. This should be sprinkled in the drills when sowing, or in the holes when planting out. Ailsa Craig and Golden Roecca are good for exhibition, and Bedfordshire Champion, James Keeping, and Brown Globe are first-rate late keeping varieties. — *NIL DESPERANDUM.*

CHRYSANTHEMUM PRINCESS VICTORIA.

GOOD white decorative Chrysanthemums are not too plentiful about Christmas time. The above variety is excellent in every way, and should become popular with market growers, as it requires little or no tying, and is a mildew-resisting variety. It is dwarf and sturdy in habit, with splendid foliage well up to the flowers, which are borne on stiff stems. The flowers are large and full. It is a creamy white in colour, sometimes tinted with lemon or pink, but if afforded a little artificial heat it opens much better and becomes white. Other good late varieties are G. W. Childs, Golden Gate, L. Canning, and W. H. Lincoln. — J. G.

HARDY FRUIT GARDEN.

Pruning Wall Fruit Trees.—*Cordons.*—If single cordons of Apples or Pears are not originally planted too thickly, they will only require at the winter pruning the side shoots shortening back to basal buds, or as near as possible to the main branch, without destroying good fruit buds. This applies to all the forms of cordons, whether grown as single vertical or diagonal stemmed plants, or those having two or more stems. The chief care is in the first formation of the forms so as not to train in main branches too closely, in no case less than a foot asunder. Where branches exist closer together than this it is advisable that the most crowded be removed. This is especially necessary with old established cordons, having clusters of spurs, which in the aggregate take up a large amount of space.

Though the branches may have apparently room enough as indicated by present appearances, yet in summer the spread of foliage is so ample that one branch will unduly shade another, and not all the fruiting spurs will be able to obtain sufficient light. Branches also trained at the orthodox distances asunder may, if crowded with spurs, be greatly benefited by having the ill-placed, projecting spurs shortened back, dead wood or weak spurs cut out. Young branches in the process of formation train straight in the direction desired.

Horizontal-trained and Espalier.—Apples, Pears, and Plums are chiefly grown in this form, and if the main branches are kept a foot to 15 inches asunder they will long continue fruitful. Annual attention must be given to reducing crowded spurs, especially not allowing those situated on the upper branches to overhang to an undue extent those below them. Shortening the strongest growing foreright shoots in summer is conducive to the plumping up of fruit spurs at the base, and to these the side shoots ought now to be pruned. The leaders of branches which have not reached their limit of space may be shortened but little, only unripe ends being removed; but if there is no more space to fill, cut closely back.

Fan and Unrestricted Trees.—Trees which do not take kindly to restricted training are best grown in fan shape. But there are restricted trees in fan form as well as unrestricted. In some positions, Pears may be grown on the former plan with branches radiating out like a fan and extending to any length the space admits of; but the points at least of the branches ought not to be closer together than a foot. The summer pruning and the winter shortening are the same as with other restricted forms.

Plums and Cherries, chiefly of the Kentish and Morello type, enjoy free extension, whereby the oldest and worn-out branches can be constantly renewed with young wood. The Cherries named bear the best fruit on well-ripened growths of the previous year, and these should be freely nailed or tied in, shoots for the purpose being specially retained at the base of the current year's bearing growths. Secure them 4 inches apart all over the trees. Previously, however, overhaul the principal branches, cutting out any exhausted parts.

Plums are better adapted for bearing fruit on older growths, shoots two and three years old bearing freely. Retain them while they remain prolific. After they cease to be so, occupy their places with younger shoots, trained in for the purpose. A combination of branches bearing natural and artificial spurs, and younger growths bearing natural spurs only, is the outcome of this method, but it is very important to guard against overcrowding.

Pruning Outdoor Vines.—Vines on walls should have the pruning completed. If the spur-furnished branches are not too old retain them, pruning back the lateral shoots to two buds, selecting the best of these when they break into growth. Also, if there be room, it is desirable to lay in a number of well-ripened canes, pruned to about 4 feet in length; these, being reserved for the purpose, will profitably utilise any vacant places, and may be trained-in to take the place of any old or exhausted branches. After pruning dress the branches and rods with Gishurst compound, 8 ozs. to the gallon of water, using warm, and brushing well

into every angle and crevice. Softsoap, 4 ozs. to the gallon, or any other effective insecticide, will also answer, the object being to destroy red spider, to which Vines on warm walls are subject.

Manuring Fruit Trees.—*Mulching.*—A liberal mulching of decayed manure conveyed to the fruiting quarters during frosty weather, and spread upon the soil over the roots of trees and bushes, will be of great benefit to all except those growing very vigorously and not bearing. Trees and bushes which bear good crops require annual assistance, either with natural or artificial manure or both combined, in order to afford substantial support to the roots. It attracts them to the surface, preventing their descending into the subsoil in search of food and moisture.

Applying Liquid Manure.—Trees on grass, which cannot so well have manure applied over the roots, may receive applications of liquid manure if such be available. In emptying cesspools or sewage tanks the contents may safely be given to established old fruit trees, diluting freely with water should it be too strong. Pour it over the roots as far as they extend.

Trees for Grafting.—Old trees intended to be grafted with improved varieties now require the branches heading down to near the point of insertion of grafts.

Collecting Scions.—The scions of the various varieties should be tied separately in bundles and labelled; then lay them in sand or soil on a cool north aspect, so that they may remain dormant until the grafting season.

FRUIT FORCING.

Vines.—*Earliest Houses.*—When the air is sharp and cold great care must be given to the ventilation, for draughts of cold air cause injury. Some ventilation, however, is necessary to prevent the leaves becoming thin and poor in texture, as in that condition they are liable to be scorched and to fall a prey to red spider. Disbud when the best shows for fruit can be distinguished; tie down the shoots before they touch the glass, taking care not to bring them down too sharply or to tie too tightly. Stop two or more joints beyond the bunch, not, however, acting on any rule-of-thumb principle, but be guided by the space at command. Do not burden the Vines with superfluous bunches, one on a lateral is sufficient, for overcropping and overcrowding the foliage are great evils. As the bunches come into flower maintain a day temperature of 70° to 75°, falling 5° however during the night, and keep the atmosphere rather drier. Supply water or liquid manure as required, but not making the soil sodden, as this often hinders root formation, gives a plentiful protrusion of aerial roots, and a sappy growth with shanking. Outside borders must have attention, which will be very slight where they have been covered with leaves and dry fern or litter, but where fermenting materials are used they must be replenished, keeping a good heap of leaves and stable litter in the reserve ground to admit of a supply being obtained readily.

Houses to Ripen Grapes in June.—Start the Vines at once. Supply the inside border thoroughly with water a few degrees warmer than the house. Liquid manure at this stage will come into use later on, as it must undergo certain changes before it can be of any use to the Vines. To economise fuel fermenting material may be used inside the house, throwing it into a heap on the floor and turning frequently to liberate the ammonia and maintain a genial warmth and moisture constantly, adding fresh material as necessary. Where fermenting materials are not available the floors and borders may be sprinkled with liquid manure daily. The temperature should be 50° to 55° by artificial means, and 65° from sun heat. If the roots are outside they will need protecting with a good thickness of dry leaves, litter, or fern. This will secure to them a much higher temperature than if there were no such protection, and is often better than fermenting materials that are not well attended to in maintaining the heat. Where the border has been exposed to cold rains and snow the temperature will be little, if any, warmer than the surrounding soil, and a good bed of fermenting material can be used with advantage, placing it on the border about 18 inches thick. This will, to some extent, warm the soil and encourage the growth of the roots, but it must be removed by the time the sun gains power to warm the soil, leaving only enough for a mulch.

Houses from which the Grapes Have been Cut.—Prune the Vines without delay. It not only avoids danger of bleeding, but insures complete rest. Cut to a plump bud as near the base as possible. Some Vines, however, do not prove satisfactory when closely pruned. The operator must act accordingly, and choose the second to fourth bud, or the best eye on firm well-ripened wood wherever situated. This will cause the spurs to become long, but that can be obtained by training a shoot from the base to displace it after bearing, and the Vine will be all the better for the extra foliage, showing it in the finish of the crop. Remove all loose bark, avoid peeling and scraping, washing the rods with softsoap and water, and after thoroughly cleansing the house dress with an insecticide. Clear away all loose soil, supply fresh lumpy loam in its place, and sprinkle about half pound of some approved fertiliser per square yard where the Vines are in need of substantial support, the material being pointed in. Keep the house as cool as possible to secure complete rest.

Late Grapes.—It is absolutely essential that Grapes hanging late be kept cool and uniform in temperature. Maintain a mean temperature of 50° for Muscats, 45° for other varieties that have finished late, with a dry atmosphere where such are hanging. Examine every bunch at least twice a week, and remove any decayed berries. Ventilate the house on fine dry mornings, and keep closed when the weather is damp, but a gentle warmth in the pipes is necessary to prevent the deposition of moisture on the berries. It is hardly possible to keep Grapes in good condition beneath leafy roofs, or even in the best structures can the Grapes

have the coolness and uniform temperature essential to their sound keeping on Vines after the sun gains power; besides, their hanging is not good for the Vines, which to do well require starting in good time to insure a satisfactory finish of their crops. The Grapes may now be removed to a dry room, where they will keep as well as on the Vines. The Vines must then be pruned, thoroughly cleansing the house. Dress the Vines, and wash every part thoroughly with some approved insecticide, applying with a brush. Air should be admitted freely in favourable weather, seeking to give the Vines as long and complete rest as possible. Where the borders are not satisfactory lift the Vines, and relay the roots in fresh compost; and where the Vines have inside and outside borders the renovation may be accomplished without loss of crop by renewing the former one year, and the latter the next.

Strawberries in Pots.—Proceed steadily with plants that are not required to give fruit at a particularly early stated time, especially in severe weather; 50° to 55° is ample at night for those started in December, and 60° to 65° by day, erring, if at all, on the safe side—the low—therefore 5° less in cold weather and the absence of sun is advisable. Ventilate whenever there is a chance. The trusses rise boldest and are strongest when the plants have the foliage well elaborated. Close atmosphere induces soft tissues, weakly organs of fructification, imperfect sets, and deformed, ill-shaped fruit.

Introduce more plants to shelves in Peach houses or vineries started about this time. Rectify the drainage of the pots, remove moss or other matter from the surface of the soil, and wash the pots clean. Surface dress with an approved fertiliser mixed with a little fine soil. If the plants do not push freely use a little superphosphate, three parts, and crushed saltpetre, one part, a thimbleful or two to a plant, according to size of pot. Noble is an excellent variety for introducing now to fruit in April, also Auguste Nicaise, the latter being the brighter fruit, equally large, prolific, and better flavoured. Royal Sovereign, President, and Sir Joseph Paxton may also be introduced, but to maintain the succession of fruit unbroken plants of La Grosse Sucrée and Vicomtesse Hericart de Thury must also be introduced at the same time.

THE FLOWER GARDEN.

Sowing Tuberous Begonia Seed.—There are two good reasons why the seed of Tuberous Begonias should be sown early. One is because such very small seed always germinates more surely before the sunshine has gained greatly in power, and the other is that unless the plants are raised early in the year they will not have attained a serviceable size at bedding-out time. Most seedsmen now supply reliable strains of Begonias for bedding out. Those with flowers borne on erect stems are rightly preferred, the drooping varieties being better adapted for vases, window boxes, and hanging baskets. If proper precautions are taken every seed should germinate, a small packet yielding 200 or 300 plants, or perhaps more, and these may be had each 4 inches or more through by the first week in June, thus insuring a good display before the summer is far advanced.

Prepare pans, in preference to pots, by carefully draining, covering the crocks with moss, on this placing some coarse soil, and finish off with about 2 inches of a very fine mixture of loam, and either leaf soil or peat in equal parts with a little sand added. The soil used ought to be perfectly free of worms and insects generally, even if this necessitates well roasting it over a fire. Make the surface perfectly level and firm, and then well moisten it either by partly immersing in water or by gentle syringings. This to be done at least six hours prior to sowing the seed. Do not surface over with silver sand, as the latter does not afford the tiny seedlings, newly germinated, any root-hold, and numbers of them perish accordingly. Sow the seeds as carefully and thinly as possible; for patches of seedlings are extremely liable to damp off wholesale.

Hotbeds, unless perfectly free of worms, are bad places, though most often selected, for Begonia raising. An upheaval of any kind or souring of the soil is likely to prove fatal to many seedlings, and the safest and best place for the pans are shelves suspended, not far from the glass, in a forcing house or plant stove. Cover them closely with squares of glass, and the latter with a good thickness of moss or brown paper. Also protect the pans from sunshine. Never once must the soil in the pans be allowed to become dry, nor should they be watered through a can. A short period of dryness would prove fatal to the sprouting seeds, and however gently water may be applied on the surface, the chances are this would have the effect of dislodging and spoiling many of the seeds or tiny seedlings. Whenever the soil is approaching dryness immerse the pans in a bucket or tank of tepid water just deep enough for the moisture to soak upwards without at the time actually reaching the surface.

The seeds sometimes germinate in a fortnight or so, the time being largely determined by their age, and directly the tiny seed leaves are detected admit light gradually, and also slightly block up the glasses, taking good care though that no sunshine shall reach the Begonias. By way of a preventive of damping either wipe or turn the glasses every morning. The seedlings will require to be pricked out long before they are large enough to be picked up with the finger and thumb.

Dwarf Lobelias.—When a good strain is procured seedlings of these are as compact, floriferous, and true to name as are cutting-raised plants of named varieties. The seed should be sown early, and much as advised in the case of Tuberous Begonias, and then there will be less likelihood of failures than there would be if sown a month or six weeks later on. If the seedlings are duly pricked out and grown on without receiving a severe check extra strong stocky plants will be ready for bedding out late in May.

THE BEE-KEEPER.

MAKING CANDY.

OWING to the mild weather experienced throughout the country many colonies of bees have become short of stores. It is now a well-known fact that much less food is consumed by bees when there is a low temperature throughout the winter than when the weather is mild, as it has been up to the present time. It is therefore advisable to supply the bees with stores in the best possible condition, so that they may take it without becoming chilled. But how is this to be done?

If given in the form of syrup the bees will not take it readily, and if an excess of moisture is taken into the hive at this season dysentery will follow. If dry sugar feeding is practised, and a sharp spell of frost should set in, the bees will starve, although there may be an ample supply of sugar within a few inches of the cluster. The best possible food at this season is soft candy where feeding is really necessary. But from inquiries recently to hand some bee-keepers have found a difficulty in making soft candy.

In making candy it is as well to bear the fact in mind that it is much easier to make it hard than to keep it soft. If made too hard the bees cannot masticate it, and the first warm day that comes they will set to work and remove it from the hive. The two chief points to be observed are not to boil it too long, and after its removal from the fire to keep it well stirred. An enamelled iron preserving pan answers the purpose admirably; fine granulated sugar should be used in the proportion of 6 lbs. of sugar to one imperial pint of soft water, into which must be stirred one teaspoonful of cream of tartar.

The water should be first put in the pan, and the sugar gradually added after being placed on the fire, keeping it constantly stirred until it boils. Care must be taken that it does not boil over the side of the pan; to prevent this it is an advantage to withdraw slightly from the fire, but not sufficient to prevent it boiling. Continue stirring until the froth, which at first will cover the whole mass, has disappeared. When it has boiled two or three minutes lift out a teaspoonful and drop it into a cup of cold water, which has been placed in readiness. If it remains at the bottom of the teacup like thick paste it is in the right condition for removal from the fire. If, on the contrary, it mixes readily with the water, it has not been boiled sufficiently, and the same operation must be repeated. If boiled too long it will be crisp and hard, and no after treatment will make it soft unless more water is added, and it is again boiled as above.

After the removal of the pan from the fire it will be an advantage to place it in a tub of cold water, care being taken that the water does not flow over the side of the pan and thus become mixed with the sugar. Continue the stirring process, and in a few minutes it will have a greasy appearance of a dirty grey colour, afterwards becoming quite white.

Care must be taken that it does not become too stiff before being poured into shallow dishes, which should have been previously prepared by placing a sheet of paper in each. The advantage of using paper will be at once seen after the candy has become cold, by the readiness with which it may be removed from the vessels in which it was poured. The paper will adhere closely to the candy, and the dishes may be again used for any purpose required. If the operation has been carefully carried out it will result in a fine-grained soft candy, which will be readily taken by the bees, and bee keepers will not complain of their bees casting the candy out of their hives.

HOW TO FEED BEES WITH CANDY.

It has been necessary to give clear instructions as to making candy, but quite as much care is essential in supplying bees with the necessary food, as at this season more than any other they should not be disturbed if it can be avoided. Candy must always be placed directly over the cluster. Bees at this season will be found snugly clustered in the middle of the hive. If a strong colony of bees be examined at the end of the honey flow, the outside combs in the hive are full of sealed stores; but examine them a couple of months later, and the honey will be found to have all disappeared from the extreme outside combs; internally they are the same as when previously examined.

Why is this? Because the bees know full well that if their food supply is stored so far away from the cluster, and a spell of severe weather set in, they would be unable to reach it, and the result would be death from starvation. Bees never make this mistake when left to their own devices. It is well, therefore, to imitate Nature as far as possible. For this reason we place the candy so that the bees may reach it without any danger of becoming chilled.

I prefer to cut a hole in the quilt, turn the lap back, and place the cake of candy over the aperture. When this is done an extra thickness

of some warm material should be placed directly over it, care being taken that there are no air spaces round the edges of the quilt.

If the bees are in good condition and kept warm, and the candy is made according to the above directions, the bees will often take it in preference to the sealed stores they may have in their hive, wisely taking the extra supply of food provided for them, they will then fall back on their stored supplies when this fails. An extra supply of candy may be given as often as necessary.—AN ENGLISH BEE-KEEPER.

* All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

A Curious Potato (W. Brown).—Potatoes, such as the one you have sent, are not so uncommon as you appear to think. We have seen cases of it before, and will give further particulars relative to it in our next issue.

Lawn Manure (T. C. C.).—Your question was answered last week. You do not repeat the formula, which was not preserved. If the soil is of a cold and wet nature withhold the salt and use sulphate of ammonia instead of nitrate of soda in the spring.

Mistletoe on Apple Trees (M. F.).—We advise you to try the two methods suggested below with several seeds, of which some may be expected to germinate. The berries should be inserted in a notch cut in the bark on the under side of a branch. Avoid crushing the seed, and have the embryo directed towards the branch. To prevent birds disturbing the seeds after being placed in position cover with tiffany or other light material. The seeds may also be fastened to a smooth part of the tree by the sticky substance surrounding them, but protected from birds. Insert the seeds at once.

Trees and Shrubs that Rabbits will not Eat During a Severe Winter (G. W.).—The following trees and shrubs were not injured with us during several severe winters, in pleasure grounds where both hares and rabbits abounded:—Alders, Andromedas, Birches, Bitter Willow, *Box, Corsican Pine, Irish Yews, Kalmias, Periwinkles, *Rhododendrons, and *Spurge Laurels. What they will not eat in severe weather, when there is little choice, or, say, only the above, we have no experience, save that of those marked with an asterisk only survived stamping by the rabbits, the Periwinkles being buried beneath snow, but if eaten off it would not matter a great deal as they spring up again from the roots. Rhododendrons, all points considered, are the best. Several trees and shrubs the animals only nibbled, but they had choice of many hundred species, which makes just all the difference.

Trachelium coeruleum (Nemo).—This plant is a native of the South of Europe, and though moderately hardy it suffers from unusually severe winters, therefore it is desirable in most cases to preserve a plant or two under glass; but it is easily raised from seed, and seedlings flower the same season. Allied to the Campanula, it nevertheless differs from many of that genus in its habit of growth; it does not throw up suckers like most of that family, but produces side shoots, which make excellent slips or cuttings. These, if put into a cold pit or under a hand-glass, where some protection can be afforded them in winter, make good plants in the following spring.

Cropping Vines (W.).—Your question as put, and in the absence of information as to the age and condition of the Vines which have been replanted in fresh soil, and the state of the roots, does not admit of a definite reply as to "how many bunches the Vine should be allowed to carry this year." Weakly Vines produce $\frac{1}{2}$ lb. bunches, strong healthy Vines bunches six times that weight. We can only advise you to let the Vines start very steadily without any forcing. If the roots were healthy and abundant a crop equal to about half that which finished well last season might not be too heavy for them. It will be safer to err in under than over-cropping, and then, if all goes well with the Vines, they may be expected to give compensation in future years. Overstraining them this summer would be a great mistake that may have far-reaching consequences.

Dahlias Showing "Eyes" in the Flowers (F. S. C.).—The chief cause of Dahlias having "eyes" is usually lack of that steady development of the plant so essential to the proper building up of the flower, and is best avoided by a proper preparation of the soil, not using freshly manured ground, but having it in good heart, deeply stirred and in good tilth. This will secure sturdy growth and well formed blooms provided the plants are given plenty of room and sturdy plants are put out in proper time. Wet seasons tend to encourage the production of "eyes," and too severe disbudding acts similarly by inducing grossness of plant, also weakly cuttings seldom throw good flowers. This should be avoided by selecting short-jointed cuttings. The tubers you have are more likely to give the proper sort of cuttings than any tubers you may purchase, and you may propagate from them with every confidence, only give the plants plenty of room, and keep the growths fairly thin.

Increasing Ficus elastica (F. D. H.).—You will find the present time is suitable for propagating this plant, either by shoots taken off with a shoot or by eyes. When it is propagated by eyes they should be taken with a leaf attached to each, and be placed in silver sand to keep them from bleeding. Insert them in small pots well drained, in a mixture of peat and cocoa-nut fibre, and plunge in a strong bottom heat of 90°, with a little sand under each cutting. If they are not placed in a strong bottom heat the eyes will not break. When the eyes have rooted and commenced growing they should be repotted into 48-sized pots, in equal parts of turfy loam and peat, with sufficient sand to keep the soil open. The plants should be placed in a temperature of about 70°, and be syringed frequently; occasionally sponging the foliage is also highly beneficial. The plants should not be allowed to become root-bound until they have grown to the allotted size, when they will be greatly benefited by liberal supplies of liquid manure. During their growing season they should never be allowed to become dry at the roots, as dryness causes the leaves to turn yellow, and spoils the beauty of the plants. Shoots taken off with a heel will make plants much quicker than raising them from eyes; and it is the safest plan, for if strong bottom heat is not afforded, the eyes, as before mentioned, will not break into growth. When only a few plants of rapid growth are required we advise that they be raised from cuttings, but when a great number of small plants is required the mode of raising them from eyes must be adopted.

Vine Weevil Grubs Infesting Roots of Adiantum cuneatum (C. L.).—We have communicated with the correspondent referred to. He is unable to account for the corrosive sublimate solution, 1 oz. to 6 gallons of water, failing to destroy these pests, except on the supposition that the article differed from that which he found successful, or that the poison was not properly dissolved in hot water. The grubs are among the most difficult to kill, as they nestle in an earth cavity, with the head coiled under the tail, the air cell formed by the coil of the body throwing off solutions, aided by the oily nature of the skins of the larvæ. In most serious infestations which have come under our notice we have found that the potting was too light and the soil not kept constantly and uniformly moist. Some persons find one remedy the best, some another. We have records of success by the use of hot water—temp. 140° to 145°. This would destroy some plants, but has not injured Adiantums during what may be termed their resting period, but the soil must be fairly moist. Clibran's Eucharis mite killer and Bentley's spidicide have also been found effectual by cultivators, applied according to the vendors' directions. The soil ought not to be dry when they are used, and it is best to close the drainage with clay, then give sufficient of the preparation to show or stand on the surface, indicating soil saturation. We once took possession of a number of "dried off" Adiantums infested with weevil maggots. All the soil possible was removed and burned, and the roots plunged in hot water, over 140°, where they remained till the water cooled. It was a case of kill or cure. They were potted firmly, started very slowly (a few not at all), but eventually developed into as fine plants as could be desired. The soil was kept moist, summer and winter, except in some half dozen pots for trapping the stragglers, and the weevil scourge was stamped out.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow

themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (J. C. A.).—Trumpington, not nearly so good as Cox's Orange Pippin. (W. N.).—Hornsea Pearmain, a very useful Sussex Apple. (O. E.).—1, Bramley's Seedling; 2, Northern Greening; 3, Braddick's Nonpareil. (Nemo).—The Pear is Nec Plus Meuris.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (North Wales).—The Cattleya was quite dead when it reached us. Pack another one properly, and we will endeavour to assist you. (S. T. S.).—1, Zygopetalum macillare; 2, Adiantum decorum; 3, Anemia collina. (N. L.).—1, Cyathea dealbata; 2, Hypolepis distans. (D. F. F.).—1, Cypripedium Sedeni; 2, C. villosum; 3, Maxillaria picta; 4, Cypripedium insigne. (N. F. P.).—1, Polypodium aureum; 2, Adiantum mundulum; 3, A. cuneatum deflexum.

OUR EGG PRODUCTION.

We have been much interested in the letter on the above subject written by Colonel Baghot-De La Bere, and recently published in this Journal, as we have paid some attention to poultry in special relation to egg laying, and now sell about 25,000 eggs per annum.

There can be no doubt that a national poultry test such as is proposed in the above letter, if properly carried out, would settle a very knotty question, and either show farmers how to turn an extra penny, or relieve them from the stigma which now more or less attaches to them that they are both obstinate and wanting in enterprise. Farmers have been a very much advised class, the advisers generally being townspeople, and the advice almost always advocated the larger production of articles of food which they are keenly interested in seeing put on the market at cheap rates. It is therefore but natural that the farmer should be a little sceptical as to the disinterestedness of his would-be teachers, and as to the value of their advice.

As the carrying out of each test would involve the expenditure of about £20 in plant, it is apparent that only people of means who have a keen interest in the subject would be likely to take the matter up. It follows, therefore, that landowners who have land in their own occupation would be the most likely people to look to for help. They have a direct interest in everything connected with the agricultural industry, upon the success of which their very existence may be said to depend, and it is to them that Colonel Baghot-De La Bere must turn for assistance in his enterprise, and he should not do so in vain.

We do not think that farmers will be found in sufficient numbers willing to spend good money, as well as give the time and trouble necessary to properly carry out the experiments, but we hope we are mistaken, and if we are not we still hope that others with the will and power to do so will conduct the experiments for them.

Colonel Baghot-De La Bere makes the assertion, and admits that it is a bold one, that no such experiment as he suggests has ever been made, that no one has ever really tested this question, not even in a single instance. We think this cannot be absolutely correct, but would fain suggest that when any such trials have been made the results have not been very encouraging, and therefore little or nothing has been heard of them.

We have in the light of our own experience made an imaginary balance-sheet of a forty-fowl test. We have carefully estimated the various items of expenditure (the system being to buy pullets and sell hens and to do no rearing), and find that it would require a high egg average per hen to pay 1s. 6d. per head per annum, without reckoning anything at all for labour and brain work. These are our figures:—

Wire fencing, posts, &c., and labour ...	£7 5 0
Fowls' house ...	7 0 0
Tools, &c. ...	0 15 0

£15 0 0

Forty pullets at 3s. each ...	6 0 0
-------------------------------	-------

£21 0 0

Interest and depreciation on the live stock would be about one-third, on dead stock about one-fifth. Here is the balance-sheet:—

5000 eggs, at } £20	Corn and green food ...	£12 0 0
8s. per 100 }	Rent ...	1 0 0
	Grit, &c. ...	0 10 0
	Interest and depreciation, hens	2 0 0
	„ „ wire, &c....	3 0 0
	Balance ...	1 10 0
		£20 0 0

In arriving at the £12 we have charged for food, we have allowed 11 lbs. of mixed grain per day, or 5 $\frac{1}{2}$ lbs. at each meal. The mixture

at present would cost 10d. per 14 lbs. at wholesale farm prices, and at this price the grain would cost £12 per annum. This £12 would, of course, include the mixed ration of meal and roots to be used as the morning meal during autumn and winter. The roots might be a little cheaper than the grain, but the cost of grinding the latter into meal and boiling the roots would make this mixed ration cost quite as much as the corn pure and simple.

Perhaps 125 eggs per hen may be considered a low laying average, but this is what we find by experience that hens will produce when well fed and with an unlimited grass run. We can hardly think that limiting the run will increase the eggs.

Good pullets of laying breeds, such as Minorca, Leghorn, or Houdan, or first crosses of these kinds, could not be bought for less than we have allowed—viz., 3s. each, and the culls would not make more than half this price in an ordinary market. There could hardly fail to be deaths amongst the stock, and twenty pullets would have to be bought each year. It does not therefore appear that 33 per cent. is an extravagant allowance for interest on original cost and depreciation annually.

One very important question that will have to be answered, if such success attend the outcome of this test that English farmers are induced to reconsider their position as regards egg production, and to increase the supply on any large scale, is this: "If Great Britain were to increase her egg production by 1,300,000,000 annually would the price remain what it is, and would the importation of foreign eggs cease?"

We have suffered from over-production of breadstuffs, we are now threatened with over-production of meat; will the same thing apply to poultry and eggs? The glut in poultry is already with us; dressed fowls and ducks could hardly be sold at some of the Christmas markets. The frozen poultry from abroad has probably a close connection with that.

When we consider the lowness of freights from abroad, and the ease with which eggs can be conveyed when properly packed, it seems idle to suppose that our foreign egg supplies would be even appreciably reduced by any competition that can possibly be organised in this country. By all means let us encourage home production; but we must not delude ourselves into the belief that we can keep our egg market to ourselves. We might as well try to supply ourselves entirely with home made cheese; in fact, there would be quite as good a prospect of success—nay, a better one.

It will be observed we have charged nothing for labour, as it is so difficult to estimate without trial.

WORK ON THE HOME FARM.

We have had to finish leading manure over soft roads and lands, and the work has been heavy, but all is cleared off for the present, and we are glad of it.

Potatoes have risen in price and are being sold in moderate quantities for immediate delivery. The work of dressing up and weighing finds occupation for spare hands, and delivery to rails for a pair of horses. We have also been thrashing and delivering Wheat, which has also hardened in price; the rise has not been great, but it has been gradual and steadily persistent, which should be a good augury for the future.

Sellers of Potatoes just now have no trouble in making good prices at home, and will be well advised to avoid sending any away to be sold on commission. "Sell at home and do not be afraid to ask a high price," must be the motto this spring.

As Potatoes are rather small this year, the higher prices tempt us to make the ware sample smaller and thus to rob the seed of just the size which ought to be its best feature; thus we spoil both ware and seed. This argument will be all the stronger if the seed size are not required for planting purposes; for in a dear time there is always a demand for good sized seed at a fair price for eating purposes, but the tubers must not be too small or they will be useless as such.

Turnips did not suffer from the brief frost, and are splendid food for both sheep and cattle. Sheep lair is now good, and the animals are doing very well. The same may be said for cattle which have abundance of capital food. Straw certainly is a little short of bulk, but the quality is splendid, and Turnips being now plentiful, supplies all round will be ample to see us through to the young grass.

Sheep of all kinds have been very healthy the last three months, losses having been almost nil. Hoggets to be fit for killing in March must have a good supply of cake, which may now be gradually increased until 1 lb. per head per diem is reached. A little sulphur mixed in the dry food once a week is a very good thing to keep the blood in good order whilst the animals are undergoing this forcing treatment. A supply of rock salt must be always within the animals' reach.

BRITISH EGG PRODUCTION.

I HAVE read the remarks upon this subject in a recent issue from the pen of Mr. Baghot-De La Bere, and whilst I am fully alive to the importance of the matter to which he draws attention, I cannot support the methods by which he would prove, or disprove, the profitability of keeping poultry. The second condition which he lays down, "Each flock of forty shall be wired in, and confined upon an acre of grass run,"

condemns the whole thing. Firstly, it is unnatural, and consequently not a fair test; and secondly, the cost of enclosing will be a serious item. Is it to be charged as an expense? If so, the result is a foregone conclusion—viz., failure.

That fowls pay, and pay well, under proper management is easy to prove, but so far as my experience goes fowls never did, and never could, pay if enclosed with wire. I of course except fancy breeds, where the eggs are sold at high prices for sitting. The great point in the management of fowls is that they shall have fresh sweet land to run on, and a second point of great importance is shelter. When fowls are confined in a wire run it is difficult, and often impossible, to give them shelter from hot sun and storm, such as they can obtain when running at large under trees and buildings; and my experience is that, putting this matter aside, it is only a question of time, when fowls are confined, before disease makes its appearance.

The mistake that many writers upon poultry make, and which has wrecked so many poultry farmers, seems to me to show itself in this passage:—"If satisfactory results can be shown from a single flock we have something to warrant an increased number being kept, four flocks upon 4 acres, or eight upon 8 acres," and so on. My experience is quite opposed to this; forty fowls, with a free run on grass and shelter of buildings and bushes, thrive and pay; double the number, with the same advantages, still pay, but not nearly so well, and with forty fowls running at large, and forty in wire pens, those in the pens lose just about as much as the others gain.

This is a brief summary of my experience. It is perhaps not fair to compare my runs, where ten to fifteen fowls had some 600 square yards of grass, divided into two yards so as to give change, with a run of an acre for forty fowls; but I think the extra cost of wiring an acre of land for this number of fowls would be more adverse to the balance sheet than the fact of the run being somewhat restricted.

To prove that fowls pay under proper conditions is easy. They paid sixty years ago, when corn was one-third to twice the present price, and eggs just about one-third cheaper; and if it can be shown that eggs were produced at a profit under those conditions, we need scarcely go further. I have many a time heard my father state that for years when he was a boy he kept himself entirely with the produce of his poultry, and would accept no pocket money, or even journey money, unless every penny were accounted for, so that he might prove the fact. He had some six or seven flocks of fowls, housed in brick hen roosts, and scattered all over the parish on grass orchard land, about 100 acres; each orchard had a cottage attached to it for protection, and the women at these cottages fed his fowls and collected the eggs at 2d. per score; the corn he paid for, and only used the best quality. How much he received he never told his boys, probably fearing they might demand an increase of pocket money; nor did he know the amount of tax the eggs had to pay to the collectors before they reached him. The fowls he kept were pure-bred Gold and Silver Pencil Hamburgs, and a few Cochins for mothers.

Coming down to later days and my own experience. For some years my wife kept fowls, having a flock of from forty to sixty about the buildings, and having a 6-acre grass field to run in. Beyond a few scraps from the kitchen (and with pigs kept these do not amount to anything serious) the fowls have no possibility of obtaining any artificial food gratis, the only stacks near being of hay; and under these conditions, paying for all food, she supplied the house with eggs for nothing and made a yearly profit of from £8 to £12. I need not say that the eggs eaten much more than paid for the time expended by a man in feeding and cleaning out the hen house.

Into the details of our failure when we attempted the multiplication of profits I need not go, it has been hinted at above, and my only reason for penning these lines is to prevent others being led away by the same fallacy.—A. H. PEARSON, *Manor House, Chilwell, Notts.*

BARR'S SEED GUIDE for 1898 IS NOW READY,

And will be Forwarded Free on Application.

Barr's Seed Guide for 1898 contains a select List of the best Vegetable Seeds and most beautiful Flower Seeds. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. Sent free on application.

Barr's 21/- Collection of the Best Vegetable Seeds contains 14 Pints of Peas (best successional sorts), 6 Pints of Beans (Broad, French, and Runners), and a liberal Assortment of other Vegetable Seeds, for One Year's supply. For full particulars see Barr's Seed Guide, free on application.

Barr's 10/6 Collection of Choice Flower Seeds contains a liberal selection of the most beautiful Annuals and Perennials. Full particulars in Barr's Seed Guide, in which will also be found many sterling Novelties for 1898.

All Seeds sent Carriage Paid on receipt of remittance.

No. 917.—VOL. XXXVI., THIRD SERIES.

SUTTON'S PEAS

FOR EARLY WORK.

SUTTON'S HARBINGER (NEW).
PER PINT, 3/6.

"First early dwarf prolific variety. Just the thing for forcing in frames or early border work. For table excellent, having the true Marrowfat flavour."—Mr. G. H. COPP, The Gardens, Holnest Park.

SUTTON'S FORCING.

PER QUART, 3/6.

"The Sutton Forcing is a grand Pea, suitable for either indoors or outside. I have tried it both in and out, and it keeps free from mildew."—Mr. J. WATTON, Gardener to Mrs. RAY.

SUTTON'S EARLY GIANT.

PER QUART, 2/6.

"Your new Pea, Giant, has done well with me this season. I consider it a grand Pea for early work both as regards flavour and productiveness."—Mr. R. PERKINS, Gardener to the Right Hon. the Countess of ELLESMERE.

SUTTON'S SEEDS
GENUINE ONLY FROM SUTTON & SONS, READING.

LEEKES! PANSIES! DAHLIAS!—NEW
LEEK, "Excelsior," 1/- Per Packet. PANSIES, 1 Dozen Tip-top Varieties, 3/6; 2 Dozen, 6/-; Seed, 1/- Per Packet. NEW BOOK ON THE "PANSY," 109 pp., 1/1. DAHLIAS, Pot Roots, 1 Dozen Superb Cactus Varieties, 4/6. New Seed and Plant List Free.
ALEX. LISTER & SON, Florists, ROTHESAY.

CHOICE NEW CHRYSANTHEMUMS.—Yellow Carnot, Western King, Mrs. S. C. Probin, Mrs. G. W. Palmer, and many other grand novelties, including M. Calvat's varieties of 1897, at moderate prices. Catalogue of 700 varieties free.—J. W. COLE, Midland Road Nursery, Peterborough.

IMPORTANT TO MUSHROOM GROWERS.—CUTHBERT'S SPECIALITE MUSHROOM SPAWN. Always alike; most productive. Hundreds of Testimonials. Per Bushel, 5/-.—R. & G. CUTHBERT, Seed, Bulb, and Plant Merchants, Southgate, N. Established 1797.

GREENHOUSE SALE.—Half Price, Off Season.
7 by 5, 28/6, 38/6; 10 by 6, 42/-, 50/-; 14 by 6, 52/6, 65/-; 10 by 8, 52/6, 58/6; 14 by 10, 75/-, 87/6; 20 by 10, 95/-, £5 10/-. FRAMES, 8/9, 14/6, 22/6. FOWL HOUSES, 8/9, 10/9, 14/6. Approval.—HYPOLITE, DEPTFORD.

HEATING APPARATUS.—Medals 1875 and 1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2/6; post free, 2/10.—JONES and ATTWOOD, Stourbridge.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd., Leeds.**

COTTAGE GARDENING; being an Essay to which the Royal Horticultural Society awarded Mr. W. EGERTON HUBBARD'S Prize, February 16th, 1870. By E. W. BADGER. Third Edition. Price 3d.; post free, 3½d.—JOURNAL OF HORTICULTURE OFFICE, 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

GREENHOUSES from £3 8/-. VINERIES, CONSERVATORIES, well-made FRAMES, painted or glazed, from 21/-. Illustrated Price Lists free. MAKER TO H.M. THE QUEEN and H.R.H. THE PRINCE OF WALES.

THURSDAY, JANUARY 20, 1898.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

DIGGING AND TRENCHING.

SPRING V. WINTER.

THERE has recently been some discussion on the benefits derived from digging or trenching ground for vegetable culture in autumn or early winter as compared with the effects of the same operations when performed in spring. I believe the chief reasons in favour of doing the work in winter is the idea that work is forwarded and the more complete disintegration of the soil effected by frosts, and thus rendering the staple more suitable for the operations of cropping in spring. After a long and varied experience, my conviction is that the season to be recommended for this work, in order to realise the object named, depends entirely on the nature of the soil and subsoil, as well as the rainfall of the district.

Given a heavy tenacious soil and a great rainfall, my experience leads me to recommend delay of the work till spring. Under such circumstances I have never found that winter digging resulted in anything but unsatisfactory results; nor do I think that the advancement of work is gained by it to any significant degree, or that the teachings of natural philosophy can be set aside in this case any more than in any other—namely, that a loose porous body of material holds more water than one that is more solid and compact; and the idea that frost finds its way more easily and into a greater depth in loose soil than it does into such as is more compressed is just as far off the mark as to say that a sponge that is in a state of compression has the same power of holding water as it has when in a state of expansion, or that a linen fabric prevents the radiation of heat as effectually as a woollen one. The laws that regulate these things are inexorable, and act powerfully in producing results that tell against the recommendation of the winter tillage of heavy soils in wet districts.

"Circumstances alter cases." When an under gardener at Carstairs House, in 1838, I learned to practise autumn digging and trenching. The soil of this garden was what is known as light and sandy, and never held moisture in suspension at

No. 2573.—VOL. XCVIII., OLD SERIES.

any season to an extent that rendered it otherwise than in a fit state for seeding and planting, and could be turned over with the spade to any desired depth any day in the year with good results. On moving from this garden to go under the late Mr. Turnbull, at Bothwell Castle, where general gardening at that time was in the foremost rank, and I may say vegetable culture specially so, I was rather surprised at first that autumn or winter tillage was never thought of. The soil was a heavy tenacious one, and the rainfall very considerable. All other work was vigorously pushed on in winter, and the digging, but mostly trenching, was not commenced till spring. Under this order of matters I do not think the work was materially, if at all, retarded. Beyond all doubt under this system, which was the result of the observation of a very shrewd and energetic man, the ground was always found in far better condition in spring for the operations of the spade and general cropping. In my own practice, as a head gardener for fifty years, and in two instances having to do with large gardens of soil inclining to clay, my experience has been the same.

The idea that the pulverising influence of frosts extends more deeply into loose soil is a fallacy that I had a striking example of in a winter when there was an unbroken frost of fourteen weeks, with very little snow on the ground. In trenching a quarter of heavy soil in spring, lumps of frozen soil were thrown up on to the surface from a depth of quite 2 feet, while some ground that had been broken up before the commencement of the frost, the frost had not penetrated nearly so deep. I have invariably found that such ground, if turned over in autumn, has been far longer in drying and becoming amenable to the action of garden tools and more difficult to get ready for seeding and planting than when left in a firm condition till spring.

The principles and laws involved in this case are precisely the same as those which have taught the farmer not to plough heavy land from which Turnips have been removed—and which he calls “red land”—in wet weather, but makes him shift his ploughs to firm grass land, or what is termed “lee” in Scotland, that can be turned over in a condition in which it holds less water in suspension than “loose” land does. I believe that all who have cultivated heavy weald land have experience that would corroborate these observations. Such experience is exactly what anyone with some knowledge of natural philosophy, or the laws that govern matter, might expect to realise without much experience.

I have said that loose soil holds more water in suspension than the same soil can hold when in a more compressed condition. Its very looseness prevents the more rapid evaporation of the water, on the same principle that surface stirring in warm weather conserves the moisture for the use of the plant in warm summers. Hence winter trenching delays the drying of the tillage in spring. The power of this same law prevents the radiation of heat, and consequently prevents the more rapid entrance of frosty air into the depths of the soil, just the same as an iron bar conducts heat more rapidly than a wooden one. Hence, by leaving the ground untrenched till spring, the beneficial effects of frost to a greater depth is the result, as compared with the opposite practice.

If these few remarks on this, if somewhat simple yet important subject, will lead some of my younger brethren who have not yet, to some extent, studied the domain of natural philosophy in so far as it bears on our gardening, they will not be in vain. A knowledge of these laws will open up a new world—so to speak—to them, and one that will throw great light on the rights and wrongs, the whys and wherefores, of their everyday work, and will be to them a source of the deepest interest.

If I may go a little further, there is a volume I would recommend them to get and study—namely, “The Infinitely Great and the Infinitely Little.” It would be an eye-opener to many of your numerous young readers, and would help to lead them to see that a life that is worth living does not depend on “bread alone,” and would teach them much of the mysterious splendour (if I may be allowed the term) of Nature. The garden affords peculiar opportunities for such a rich enjoyment, and which may issue in most instructive results.—D. THOMSON.

THE FIRST OF THE FLOWERS.

IN one of his last essays, “The Hours of Spring,” Richard Jefferies speaks of the “Sweet Briar wind” which brought with it the breaking up of a long hard frost and the advent of the growth of spring. Clouded over, as his words seem by ill-health and an unavailing longing to be once more amid the sights and sounds of the open air, they do us good at these times. We see our lost Nature-lover at the window-pane, looking out upon the frozen earth and the war of snow and wind. We see him with his weary eyes once more lit up with hope and joy as they drink in the signs of the coming of spring, and his ears are filled with the songs of the feathered minstrels. We can enter into the spirit of his mood, even if we cannot hope to attain to his knowledge of Nature’s ways or his mastery of the English tongue, which touches and uplifts us as we read.

No “Sweet Briar wind” is it to-day which comes from the south-west, but one fierce and rain-laden, like so many we have had this winter. No brightness does it bring, but, instead, fog and flying rain, with dull grey skies. Yesterday the wind was high, and brought with it clearer skies and long-wished-for sunshine. Pleasant was it to see the sun glinting on sea and mountain. Pleasant was it to be in the garden to observe the promise of spring. Faint and sickly as was the sun, and though the clouds hung heavily over the mountain top, it gave us cheer while it lasted, and lit up the few flowers of the time. Not a Crocus could open, so feeble were the rays, but their tiny cones were brightened as we looked vainly for the outspreading of their segments.

The Winter Jasmine was lit up, too, and a few Snowdrops spread out their petals as if to invite to sip from their treasures any adventurous bee which might dare the season’s frowns in search of food. But not one came, and these and other flowers too soon felt the coming of the storm. Mayhap they saw, as we did, the clouds flying from the south-west, and when the moon uprose the lurid colours which shone round her disc. Who knows? Too long have they suffered from storm and rain this season, and many, like the pale Primrose, have been “born to die unmarried,” and have fallen a prey to the combined forces of rain and wind. The garden is not cheering when it is sodden with rain, when planting is worse than vain, and when everything is a-drip and dreary. It is not, however, our aim nor desire to linger longer over the discomforts of the time, but even among the clouds, as Jefferies did, to seek to find the silver and the gold which will bring cheer while we await the happier spring.

The maiden Snowdrop has not been in haste this winter. Fashioned, as some of the poets have loved to fancy, from the snow, and bearing its name, there has been but little of its native element to give it birth. So might the poet say, but the gardener is more prosaic, and would ascribe its dallying to another cause. But it is not yet late for the “Fair Maids of February” of the olden time—not late for the flower of the Feast of the Purification—the Snowdrop known to Parkinson and Gerard or other old time gardeners. Its time is yet to come, and we speak now of others which are wont to come before the last month of the year has begun, or those which, at times, droop their heads ere New Year’s Day.

These are late, delayed mayhap by the cold summer and the dull rainy autumn and winter days. Thus the little *Galanthus octobrensis*—a small and delicate-looking flower—has not, at the beginning of the second week of January, been fully open, although it has drooped its flowers for a week or so. The earliest Snowdrop has been *Galanthus Elsä*, originally collected by Professor Mahaffy on Mount Athos, in Greece. This was in bloom in the last days of December, and is still in flower. It must be said that *G. Elsä* is not so laggard in its ways this season as *G. octobrensis*. Again we have been disappointed in not seeing the flower of *G. Rachelæ*, another of Professor Mahaffy’s finds, and, like *G. Elsä*, named after one of his daughters. It is of more delicate constitution than the latter, but would have flowered last winter as well as this had it not been that the slugs robbed it of its petals when the flower was just above the ground, while they leave the other alone although close by. These garden pests seem to prefer the flower from Mount Hymettus, famed for its honey, rather than that from the sister height of Athos. From Shepton Mallet our leader among Snowdrop lovers—Mr. James Allen—has sent an early flowering selection from *G. byzantinus*, collected near Broussa. The season in Somerset has been more favourable than here, and flowers are consequently more advanced. My Snowdrops, received from Broussa the same year as those of Mr. Allen, are coming forward quickly now, but this selected variety is likely to be in bloom early in December in most seasons.

There are many stray Snowdrops showing their snowy segments through their green envelopment; some of these are varieties of *G. Elwesii*, but in other seasons the opening day of the year has at times shown us these in full flower. Welcome ever is the little Winter Aconite, with its golden head and Elizabethan ruff below. For days we looked in vain for the appearing of its flowers above the black wet soil, so when the first bloom, with its encircling ruff of

green, came fully into flower its welcome was a joyous one. Simple, cheap, easily grown as is the unpretending little *Eranthis hyemalis*, it is ever a gladness-giving guest, bringing with it not only its own unassuming beauty, but the promise of gayer flowers. It grows in several places, and among others a shady corner is brightened by its presence now, and when it has gone to rest the drooping white bells of the Lily of the Valley shall come to take its place. They are mingled together, and light up a darksome place in their own appointed times.

Few flowers love the sun more than do the Crocuses. The Dutch varieties have long been astir, and there are many clumps with points reared above the soil, like miniature but tender *chevaux de frise*. A harsh simile it may be; but, as yet, if you pass the hand over them they are firm and hard to the touch, even though the flowers begin to appear in little points—colourless as yet, but by-and-by to be bright as the time in which they flower. How we rejoice as we see them open to the sun! Even now, closed though they are, the heart is joyous at the thought of the future time.

But the Crocus lover is not content to wait for the great flowers from the land of canals and dykes, the land of Hyacinths and Tulips, and the array of other bulbous flowers, with which we are delighted. He must have more of the wealth of the Crocus than this, and goes farther a-field for many of the objects of his admiration. We may thus have now not only the hope of the future, but the enjoyment of the present, lessened though it is by cloud and storm and rain. One bright day among many dull ones may suffice to give us a glimpse of the gold of *Crocus vitellinus*, or of *Crocus ancyrensis*, both of which have waited awhile. Is there not, too, a bud or two on the few plants of the rare *Crocus Crewei*? A day of sunshine would open these, and reward us for weary days of waiting. Ah! the compensations gardening has. Disappointments are many, but at times they are lost and forgotten in the more than realisation of our brightest hopes. Fox's Winter Crocus (*C. hyemalis* var. *Foxi*), drenched, soaked, and disfigured, has given up the struggle for the year, but we hope to have a recompense when our eyes rest for the first time upon *C. Crewei*, of which we may have to tell again.

The white winter-flowering Heath—*Erica carnea alba*—is wreathed with its flowers. The pink variety or type (which you please to call it) is also coming into flower, though paler yet than it shall be later on. There are stray flowers on *Arabis* and *Aubrietia*; Marigolds, too, give us a touch of orange colour, but a frosty night or two cut off some Wallflowers then in bloom. There are some Hellebores and some Primroses, and it would not be difficult to find a bloom on some of the early Cyclamens, and a more careful search would reveal a few other flowers which, despite the uncongenial time, are in flower. Iris Bakeriana, one of our most delightful winter flowers, has been in bloom since before Christmas Day, and the queen of summer—the Rose—seeks to extend her reign over winter as well, for has she not given us still some pink China Roses—a flower of Longworth Rambler and one of Reine Marie Henriette, the last being deprived of a petal or two by the wind to-day?

Our tale of the time is done. It is a mingled one of joy and pain, as becomes that of the birth of the flowers. The pain is present, but the joy and the hope almost overwhelm it by their magic power.—S. ARNOTT.

EARLY STRUGGLES FOR KNOWLEDGE.

(Continued from page 4.)

THE method adopted in my studies of practical horticulture was to take up each department in turn, obtain the best books available, and work it out thoroughly; but any special work often led me into extensive researches, as an instance will show. One of the first gardening books I ever read was Wheatley's *Observations on Modern Gardening*, published in 1771. This work is scarcely known to gardeners of the present day; but I formed a high estimation of it, and it was long after when I found that Loudon had pronounced it to be "the grand fundamental and standard work on English gardening." It was partly due to this, and partly to the employment in laying out gardens, which led me to seek for the opinions of the best writers on the principles of taste, and in the pursuit at various times I bought and studied the following works:—*Analytical Inquiry into the Principles of Taste*, by Richard Payne Knight, who was brother of the celebrated President of the Royal Horticultural Society; *Essay on the Picturesque*, by Uvedale Price; *Essay on the Sublime and Beautiful*, by Burke; Gilpin's *Remarks on Forest Scenery*; Fosbrooke's *Epitome of Gilpin's Principles of the Picturesque*, and Mason's *Essay on Design in Gardening*.

Then on the practical side I worked at Kemp's *How to Lay Out a Garden*, and Smith's *Parks and Pleasure Grounds*, both useful books, and to these must be added Loudon's elaborate works. The course of study described first awakened a love of trees, and not only induced me to study them at the time, but it has been my pleasure also during the past twenty years. Loudon's *Encyclopædia of Trees and Shrubs* and

Brown's *Forester* were the two books I found (and still find) the most useful, but these were not procured until near the end of my probation, when I was able to devote a little more money to the purchase of books. Loudon's *Instruction for Young Gardeners* proved valuable in the early stages, and my attention was led in various directions by that work, but chiefly towards geometry, drawing, and land surveying. On the former I procured a cheap text-book and a second-hand copy of Simson's *Euclid*, and on the latter I was delighted to pick up at a stall one day a copy of Crocker's *Elements of Land Surveying*, which removed many difficulties.

As regards the principles upon which general gardening is founded, Lindley's *Theory of Horticulture* assisted greatly in a comprehension of the various practices, and another little work, *The Science and Practice of Gardening*, by G. W. Johnson, founder of the *Cottage Gardener* and co-Editor with Dr. Hogg for many years of the *Journal of Horticulture*, was studied with benefit.

In reference to special departments of gardening, fruit culture received considerable attention, for my work was largely concerned with it. The two first works I bought were Rivers' *Miniature Fruit Garden*, and the second edition of Dr. Hogg's *Fruit Manual*, which though a small volume was a very useful little book, presenting a marked contrast in size with the last edition of this celebrated cyclopædia of fruits. This was followed by William Thomson's *Practical Treatise on the Cultivation of the Grape Vine*, and David Thomson's *Fruit Culture under Glass*. From that time I bought and read many works of the older writers on fruit, quite a library in themselves, and these were followed in later years by all the best of the modern works that could be afforded. Kitchen gardening, stove and greenhouse plants, Ferns and Orchids were studied in a similar way, but need not be particularised, as sufficient has been enumerated to show the course taken. It should, however, be added that the horticultural journals were an important source of information, but for a considerable time I did not see them regularly; in the latter part of the period described I had the good fortune to see one every week, and sometimes more, and it would be difficult to estimate the advantages to be derived by gardeners, young and old, from a careful study of the admirably edited gardening periodicals.

A few words must be devoted to my botanical studies, because they greatly increased my attachment to horticulture as a calling. The first work bought is now an historical curiosity, it was entitled *An Introduction to Botany*, and the author was James Lee of The Vineyard, Hammersmith, the founder of the firm, whose name can still be seen near Addison Road Station, Kensington, on the old site, though the original nursery has been absorbed for other purposes. This book was founded upon the writings of Linnaeus, and dedicated by permission to that great naturalist in an admirably worded preface, which would indicate that "James Lee" must have been a fine type of a British horticulturist. The work, I believe, had a large sale, and assisted greatly in popularising the Linnean system. Another old work which came into my hands was *The Elements of Botany*, by Dr. B. S. Barton, which especially attracted attention by its excellent coloured plates of *Sarracenia* and *Dionæa*, but it also contained much useful information. From these I proceeded to Lindley's, Hooker's, Balfour's, Oliver's, and Masters' works; and it is not necessary to trace how my studies were gradually extended until later on I reached Sach's great Text Book. A study was also made of our native plants, and many a holiday journey was made over commons and through woods in search of British plants.

At this time, too, whenever I had a half-day's holiday I visited the parks, public and private gardens within walking distance, took notes of all I saw, and wrote them out, any doubtful matters being made the subject of careful research. A diary was kept of both work and studies, and in reading the majority of useful books I made it a rule to write down as concisely as possible what was remembered of the principles or objects of the various works, thus obtaining valuable exercise in composition.

With regard to my subsequent experience, and advanced studies pursued under more favourable circumstances, it need only be said that they have been entirely devoted to horticulture or cognate subjects, and the knowledge gained I have endeavoured to apply usefully in the service of my employers, and to the benefit of fellow workers. In the sketch of my early labours I have not dwelt upon the many difficulties and discouragements experienced, because it might appear that I wish to exalt my efforts. My struggles were due to an innate desire to gain knowledge, and raise myself in the world by that means. My father's injunction has always been in my mind, "Learn all you can of useful subjects, but learn thoroughly, observe closely, and reflect constantly." Happily my work has not been in vain, for I hold a position which so exactly accords with my taste and inclinations that I envy no man. Apart from this, however, my books and studies have yielded a never-ending pleasure. I am still a student, learning patiently from the great book of Nature, and my only wish is that I may be permitted so to continue to the end.—A WORKING STUDENT.

A DREAM OF THE FUTURE.

CHANGE of air and scene act like magic on both mind and body. Even in the depth of winter how much there is to note in this land of ours as we speed onward behind the "iron horse!" All roads seem to lead to that greatest of cities with its endless piles of bricks and mortar, and when it is reached many seem tempted to linger and enjoy the familiar gaieties which at all times prevail in the great metropolis. To me it often seems a place to avoid, or at least to leave as soon as possible, and pass onward to that fruitful garden beyond—the fair land of Kent. Towards that goal I journeyed—somewhat slowly—last Christmas Eve, and a few days spent in walking and driving about the fruit-growing districts of the Hop county supplied me with much food for after reflection, as well as ample work for the perceptive faculties during my stay there. In the matter of fruit-growing the Kentish folk have been "going ahead" during the last ten years. So much planting has been done that the whole district seems destined to become one vast fruit garden. The system of culture followed is, I noticed, improving all round, and the young plantations, just entering upon their prime, looked promising indeed for another season. Beside them the old orchards, with their stunted growth and gnarled or broken branches, cut a sorry figure. They have done their duty in the past, but cannot be expected to produce fruit of high quality when decay is already beginning in their trunks.

I left the land of sunshine to journey toward the mists which too often enshroud the Midlands, and on the way my thoughts dwelt continuously upon the progress I had noted. I think, indeed, that my sluggish imagination was stimulated at the prospects before us in this thickly populated island. When home was reached at last and sleep sought in the usual way, the mind for once gained the mastery over the tired body, the brain was active to work, to plan, but felt not the need of sleep. When this did come at last it was only to carry me to the "land of dreams," where I appeared to see a vision of the future, which I will attempt to set down, for who can tell whether or not that vision may contain some germ of prophetic truth?

I seemed to see all England at a glance; but what a change to England as we know it now! A network of railways permeated the whole country, the great towns seemed to have grown little, but a vast number of others of moderate size had sprung up with wonderful regularity throughout the country. It was summer time. The meadows, as of old, with their deep green verdure were in evidence on all sides, for the milk trade of the country had grown to enormous dimensions, light railways passed through every village, and milk was conveyed two or three times daily to surrounding towns, where a wonderful and complete system of distribution was in force. The farmers themselves seemed shrewd business men, with a prosperous look about them, being happy and contented. I seemed to miss the corn fields, but soon perceived they were things of the past, for farming was confined to the production of milk, butter, meat, and food for cattle.

The other tracts of cultivated land seemed like a series of huge gardens, which produced wonderful crops of fruit and vegetables. On all sides work was abundant, and method, industry, and science seemed as if by magic to convert every concern into a paying one. The growth and disposal of fruit appeared to have become one of the greatest of rural industries, and those pessimists of olden times who used to declare that fruit could never be largely grown in England, and that much of the land would go out of cultivation, were quite forgotten; while those strong men who, at a critical time, lost no opportunity of working and striving with all their strength to encourage extensive fruit growing on scientific principles, were looked upon as prophets of old, whose names were remembered for the good they wrought for their country—for their bloodless victories.

Then I seemed instinctively to realise what great advance had been made in the system of distribution, as well as in methods of culture. The immense advantage of combination had evidently been fully grasped. A National Society of Fruit Growers had come into existence, which society had agents for the sale of fruit in every town in Britain. To these the growers sent their produce, and after paying commission, received the full return. Telephonic communication prevented any particular town from being "glutted" while others were in want, because information about the state of the markets was constantly exchanged between every district, and the wonderful increase of speed on all railways, combined with the use of trucks fitted with cool chambers, reduced the effects of a journey of a few hundred miles to a mere trifle. Mechanical appliances having entirely done away with the necessity of manual labour, fruit as an article of food had become an absolute necessity for all classes, and consequently fruit growing was a real and important national industry. Instead of relying on America and our colonies for Apples to the same extent as now, we had enough of our own, besides exporting jam in enormous quantities, thanks to the cheapness of

sugar in England and to the natural adaptability of our sea-girt isle to the production of fruit.

The business appeared to be managed in this way. The National Society of Fruit Growers had established one or more jam factories in every fruit growing county, and whenever the ripe fruit exceeded the demand of the moment, telephonic communication directed the surplus to be sent to those factories to be utilised. Thus waste was prevented, and what at one time used to be a loss was turned into profit. The British race being a severely practical one, brought in the aid of science to improve their methods, both in regard to economy of manufacture and quality of the manufactured article, till English jams became famous throughout the world for their unequalled excellence.

Hybridists, too, seemed to have kept pace with the times, for varieties of Apples and Pears, specially adapted for growing in the climate of Britain, had been raised. I marvelled in my dream at the great size and wonderful brilliancy of colour they all possessed, the one point the foreign supplies used to beat them in. Perhaps, too, the climate had improved in consequence of the re-timbering of the land with fruit trees. It seemed at least to be so, judging by the style of dress I noticed, and the vivacity of the people, which appeared akin to that of dwellers in sunny lands. The wand of the magician had, I thought, indeed been waved over England with marvellous results, for the bright alertness, fine physique, and happy faces of those who seemed to pass before me with vivid clearness, could only be found in a land where peace and plenty dwelt. I seemed to glow with pleasure at the thought; then I awoke with a start, and lo! it was "only a dream."—ONWARD.

[Our friend is not only a good dreamer but a good worker, and if all in possession of land could turn it to account as well as he has done there would soon be a quick march "onward" towards the realisation of his ideal.]

NOTES ON VINE BORDERS.

WHILE I was reading the common-sense remarks, of "Vitis" (page 617, December 30th, 1887) on Vine borders, it occurred to me that if practical Grape-growers recorded their own failures, or what they have observed by the sudden collapse of Vines in borders which have been formed with care and the greatest of skill exercised in the formation of them, it would be as instructive to the inexperienced beginner as lengthy chapters on orthodox methods of preparing the soil and manipulation of border-making. There are often local circumstances which have to be considered in reference to this subject which are unknown in other localities, and may necessitate a complete change of action in placing drainage and soil for the roots to ramify in safety.

It is seldom one can work with success on identical lines in positions diversely situated. In low and damp-lying ground, where drainage is formed under difficulty, precaution is necessary to keep the roots from passing downwards where they would likely perish, while in elevated positions precautions have to be taken to prevent the evils which accrue from drought. I know where there are Vines in the south of England which produce excellent Grapes year after year, and are recorded to be about a hundred years old, and where the roots have gone in search of food no one could correctly state. I have also within my ken in the same latitude the failure of Vines by shanking of the Grapes where borders were formed elaborately, with all one could suppose to insure the best results; but the roots ran through the excellent soil into cold, wet, and inert clay beyond, and speedily brought failure and great disappointment. If the border had been limited and means adopted to prevent the roots from wandering I believe success would have been complete.

Many cases of this kind I could relate, but will not at present make claim on your valuable space further than record an episode relevant to keeping Vine roots within bounds—viz., an Alicante Vine, which had for thirteen years produced excellent crops of Grapes; but two years ago gross growth developed—the berries were larger but badly flavoured, and would not keep, as they had always done, till April. During the past season no improvement took place. We went in search of the mischief by digging down by the side of the wall which enclosed the border, and found the delinquent roots had pushed their way down by the side of the wall till they reached cold wet unhealthy clay. They were in abundance, and no doubt had been drawing up moisture with nothing in it, or worse, which rendered the fruit so obnoxious. All the roots had to be severed, and bricks built to prevent further egress.

All the Apple trees here have been placed on foundations of bricks to prevent downward growth, and canker has ceased. There have been abundant crops for over a dozen years; old and young trees alike respond favourably to the good practice of keeping the feeders under complete control.—M. T., Carron, N.B.

LÆLIA ANCEPS MRS. DE BARRI CRAWSHAY.

THE number of varieties of *Lælia anceps* is very considerable, and several of them are of more than ordinary merit. So useful and so beautiful is this Orchid, however, that there is plenty of room for more provided they are equal or superior in quality to those already known and appreciated. One of the latest additions, and at the same time one of the handsomest, is *L. a.* Mrs. de Barri Crawshay, which was exhibited at the Royal Horticultural Society's Show at the Drill Hall on December 14th by de Barri Crawshay, Esq., Sevenoaks. On this date the Orchid Committee recommended an award of merit, and there can be no doubt the honour was deserved. As may be seen by reference to the woodcut (fig. 9), the form of the flower is very fine, and it need scarcely be said that in size and substance it lacked little of being perfect. The sepals and petals are very rich purplish rose, while the front lobe of the lip is deep velvety purplish crimson. The throat has veins of bright crimson on a pale yellow ground. It is a decided acquisition, and was very greatly admired on the day of exhibition.

POTTING ORCHIDS.

SUCCESS in Orchid growing largely depends upon atmospheric conditions, proper grouping as to temperature, and other details, but unless they are properly potted in the first instance the usefulness of these is to a certain extent negatived. Potting, as I here use the term, has a very wide significance; it means providing a root hold for plants of very different habits, with many types of roots, and from many different countries. Before commencing, then, to provide a new rooting medium for a varied collection, a little thought must be given to the style of root and the class of material they are most likely to thrive in.

First there is the large fleshy root of the majority of distichous-leaved plants, as the *Vanda*, *Aërides*, *Angræcum*, and *Saccolabium* species. The majority of these show a great partiality for peat, but much prefer the elastic light sphagnum moss of our shady copses and woods. It is naturally a bog plant, but grows often on the banks of streams, and the quality from such positions is always superior to any found over deeper water, or rather mud. It should be used fresh and in a living state, picked free of all foreign substances, as weeds, decayed leaves, sticks, and other refuse. The neglect of this often leads to the introduction of fungus and other ills that give considerable trouble afterwards. For the majority of kinds charcoal or clean crocks should be added or mixed with the moss as potting proceeds.

The depth of moss required by various kinds is only to be judged by experience of the size and quality of the roots, but in all cases it is safer to be on the side of thinness rather than otherwise. Such large growing, vigorous looking kinds as *Aërides obovatum*, *Angræcum eburneum*, *Saccolabium Blumei*, or *Vanda suavis* will push through a thickness that would be fatal to *Aërides roseum*, *Angræcum modestum*, *Saccolabium bellinum*, or *Vanda cœrulescens*. Then, according to the habit of these, some do best in large pots, others again prefer baskets, while many of the least growers are best suited in the small pans so much used now for suspending.

Without detailing the kinds suitable for each mode a hint or two on carrying out the work may be useful. The large kinds should have the roots spread out as far as possible, and all air roots must be brought under the influence of the compost. By this I do not mean that those outside the pot should be broken and snapped about in order to get them inside, this checking the plants in every case, and often

killing the individual roots. When the plants are unhealthy through any cause this should be easily found at potting time. Some of the taller growers show a disposition to give way at the base of the stem, and this may be got over by cutting the end off to where it is sound. This plan is often resorted to when plants lose the lower leaves, the shortening of the stems allowing them to be set lower in the pots.

Basket plants require much care in handling, as in most cases the roots will be found to have taken hold of the bars which they twine around and are difficult to remove. The old basket must be taken to pieces by drawing out the corner wires and sawing the rods through at convenient intervals. These, with the roots clinging, may sometimes be placed entire in the new baskets, but it is not well to overdo this, as wood buried in sphagnum often produces a troublesome white fungus difficult to get rid of. Any decaying roots may be

FIG. 9.—*LÆLIA ANCEPS* MRS. DE BARRI CRAWSHAY.

taken off, this being necessary with any and every kind of Orchid. Those liking small pans require the most care, as there is not the same chance of fixing them as where the receptacles are larger.

Put the drainage in the pans ready, and then break the old one if the plant does not slip out easily. Although the roots may not be very plentiful outside, there are plenty, as a rule, clinging to the inside, and if any force is used these are bound to be torn as the plant comes out. Orchid roots may sometimes be loosened by soaking with water as hot as it is safe to use it, but this applies more to long straight ones on the outside of pots or on the stage than to smaller ones coiled around the insides of pots or pans. It will be found, as a rule, the larger the roots are, the rougher and deeper the compost required, those having smaller less fleshy ones being best suited in a shallower less divided medium.

In the latter category may be mentioned the deciduous section of Dendrobiums, Oncidium tigrinum, and others, many of the New Grenadan Odontoglossums, Masdevallias, and, in fact, the majority of pseudo-bulbous Orchids. But in most cases these will differ from the last mentioned in that they nearly all like a good per-centage of fibry peat mixed with the sphagnum moss. This must be cut some time in advance, well dried, and all earth and sand shaken or beaten out of it. The largest of the bracken roots must also be taken out, as they grow freely in the moist heat of the Orchid house. Orchids that like a proportion of loam as well as the above ingredients are many, and include the majority of Cymbidiums, Sobralias, Lycastes, and a few Zygopetalums.

These, as a rule, like large roomy pots, good drainage, and a very rough open compost. Lycastes, it is true, do with less room than the others, so do Anguloas, but the quality of the compost does not differ materially in any. In addition to those already mentioned there are Orchids naturally terrestrial, as many of the Indian Cypripediums, others that are naturally epiphytal, or partly so, but thrive under cultivation in a terrestrial compost. Pleiones, Thunias, Calanthes all belong to the latter, and should be potted in peat, loam, and chopped moss in varied proportions, according to the liking of the individual kinds. Some of these have recently been treated on in these pages, and others will as occasion arises.—H. R. R.

SIMILARITY OF LIFE IN THE VEGETABLE AND ANIMAL KINGDOMS.

(Continued from page 26.)

LIFE IN THE WATERY ELEMENT.

AQUATIC plants, marine or fresh water, appear to occupy the same relative position as the countless forms of animal life existing under similar conditions. Here may be remarked plants which pass a submerged existence, and others—the Nymphæas, for instance—which, like the Amphibia, seek for air at the surface. With these the resting period is, of course, one of total submergence; but we have again a connecting link between aquatic and terrestrial plant life in those members of it which, perforce of circumstances, rest during normal periods of drought. This is in no way remarkable, only inasmuch as is to be found a kind of mimicry by animals possessed of voluntary motion (which all are not) in a lively degree.

A notable example is that of a certain species of fish which pass a period of suspended animation imbedded in the hard-baked mud of a river bed until awakened by a return of the normal element. The cause of this, however, may be easier to trace than in the case of the alligator, an example of which is detailed by Humboldt, who speaks of a Spanish gentleman, one who had entertained him during his South American travels, having witnessed an extraordinary scene. He and a companion, whilst sleeping in a temporary building erected on the bank of a river which had been unconsciously built over a buried specimen of the obnoxious saurian, were rudely awakened in the night by its struggles for freedom, which eventually having obtained, it snapped viciously at a dog as it decamped to the river.

With terrestrial plants, as with terrestrial animals, death by drowning can take place in a comparatively limited period, many when submerged for a certain time becoming blackened and decomposed. This I have experienced with Chrysanthemum cuttings totally submerged in a tank from twenty-four to forty-eight hours, when death has resulted, they having, in fact, been asphyxiated. In spite of this, it appears quite reasonable to suppose that both plants and animals are prompted by Nature to make more or less effort to accommodate themselves to circumstances foreign to what may be regarded as an essential condition of life. An interesting experiment was made by Mr. Burbidge with a plant of Pistia stratiotes in the College Botanic Gardens, Dublin. This when potted and treated as a terrestrial plant showed under these abnormal conditions a considerable reduction of the bladder-like construction, and every appearance of this part becoming metamorphosed into woody stems.

Evolution in both kingdoms is acknowledged to be distinctly traceable in fossil remains, which, like steps in a ladder, bring us up to, not the highest possible, but practically the best possible, to the particular age. This may be termed natural accommodation, or better still, perhaps, adaptability to the circumstances of life. Darwin, in his attempts to fathom the vast abyss of ages, concluded, one might rightly infer, I think, that he, at least in his own opinion, had unravelled the two strands of life till they were no longer divisible, and but one unit of creative force remained to represent a common origin. However we may regard this, or whether from the depths of primeval shadow it is too obscure for present purposes to be regarded at all, the dual aspect of life in the watery element presents in the lower forms of each a similar mysterious convergence.

The Greek designation, Zoophyte, signifying animal-plant, illus-

trates this, and going even further into the very abyss of obscure life contemporaneously existing we find in Dr. Wright's edition of "The Ocean World," by Louis Figuier, the question asked anent the Protozoa (literally first animal). "Has the Protozoon sentiment, feeling, perception? Has it consciousness, sense, sensibility? . . . do they know what takes place at the three-thousandth part of an inch from their microscopic bodies? To the Creator alone does the knowledge of this mystery belong." The similarity of life in the two kingdoms under this phase may, I think, be admitted, but more pertinent things claim our attention.

SIMILARITY IN SUSCEPTIBILITY.

Apart from sensibility brief attention may be given to the susceptibility of plants to injury from causes similarly affecting animal life. The action of various poisons exemplifies this in a remarkable degree. Dr. Lindley treats of this very conclusively in his "Introduction to Botany," commencing this particular study by saying, "The vitality of plants seems to depend upon the existence of an irritability which, although far inferior to that of animals, is, nevertheless, of an analogous character." The late doctor seemed to be perfectly in accord with the opinion of M. Marcet derived from a series of experiments, who arrived at the conclusion that "metallic poisons act upon vegetables nearly as they do upon animals; they appear to be absorbed and carried into different parts of a plant, altering and destroying the vessels by corrosive power." Also "That vegetable poisons, especially those that have been proved to destroy animals by their action upon the nervous system, also cause the death of plants, whence it is inferred that there exists in the latter a system of organs which is affected by poisons, nearly as the nervous system of animals." These results were confirmed by the further experiments of Macaire, the importance of which is duly recognised by Dr. Lindley.

Were anything wanting here to further establish the identity of the two kingdoms, so far as this phenomena is concerned, Lindley's practical proofs provide it in the ascertained fact that "those mineral substances, which are innocuous to animals, are harmless to vegetables also." Further, it is adduced that Marcet's observations "proved that narcotic and irritating poisons produce an effect upon vegetables altogether analogous to that which they produce upon animals;" and lastly, in connection with this, "The very valuable experiments with gases by Turner and Christison . . . lead to the same conclusion."

The inherent powers possessed by plants in reparation of injury need scarcely be dwelt upon, but where these natural efforts are afforded aid unexpected results are often obtained. In the case of a noble Beech, which had far up its trunk a large elliptical cavity, and by which, owing to the lodgment of water, its life threatened to be considerably foreshortened, this power of reparation was curiously displayed, and but a few years elapsed after the face of the cavity being closed up with bricks and cement ere the skin, if we may so term it, had entirely closed over the gaping wound, and to all outward appearance our Beech was as sound a specimen as it was grand in its proportions.—INVICTA.

(To be continued.)

CULTURE OF LAPAGERIAS.

THE Lapageria is one of the most useful and ornamental of all greenhouse climbers, and may be as easily and successfully cultivated by the amateur as the professional gardener in town or country. That it will succeed well in smoky town gardens I have had abundant proof from numerous healthy specimens I am familiar with growing in some of the blackest parts of smoky London. Anyone having a greenhouse containing hot-water pipes sufficient to keep out frost during the winter months may with confidence enter upon the cultivation of this beautiful plant. From April until November no artificial heat whatever is required, and from November to April no more than is sufficient to exclude from the house the two great enemies to plant growth during winter—viz., damp and frost.

I have studied the plant and its requirements closely for a great number of years, and have witnessed many cases of success, and also many failures in its cultivation; and almost invariably I have found that the main cause of the latter was that the roots of the plant had been kept too cold and wet during winter. During summer the plant, if healthy, forms abundance of white fleshy roots, in some cases nearly as thick as a pencil, which decay quickly, perish, and almost entirely disappear during winter if the compost in which they are growing becomes wet and cold, and approaches being what is called "sour." The same sort of thing is frequently experienced by Grape growers, when the roots of the Vine have mostly found their way to the bottom of the border, and the same is cold and wet.

What is especially required for the well doing of the plant is that these roots, produced in such profusion during summer, shall be preserved through the winter, and this is most readily done by planting it in such a position that they may be slightly warmed by the hot-

water pipes, which should be near to, but not in actual contact with, the box or pot in which the plant is growing.

To those about to commence its cultivation I will now endeavour to give, as plainly as I can, particulars as to the system I would recommend, and which I have myself proved to be most thoroughly and remarkably successful. In procuring the plants, which may be purchased at almost any of the large nurseries, I would advise that if possible one each of the two most useful varieties—viz., *L. alba* and *L. rosea superba*, or as it is sometimes called, *L. rubra*, be procured and planted, either together or separately, as is most convenient. In either case the growths should be allowed to intermingle, as the effect when the plants are in bloom is much finer by so doing. Good plants may be procured of either variety at a very reasonable cost. The older form, *L. rosea*, is cheaper than either of those just mentioned, but is very much inferior.

As soon as the plants are procured a permanent position should be selected for them to occupy, and a box or boxes procured to fit such position. A suitable size for boxes is 3 feet long, 1 foot 6 inches wide, and 15 inches deep if for one plant, but the length and breadth may be modified to suit the position at the cultivator's disposal. If two plants are intended to be planted in one box, it will require to be enlarged either in length or in breadth, but preferably in length.

An angle of the house is usually the most suitable position, and the box should then be so fixed that its bottom is 2 to 3 inches above the hot-water pipes; this to be a clear air space between, so that the box is in no way in contact with the pipes. Two inches of crocks, with some lumps of charcoal, must then be placed over the box bottom, in which a number of holes should be bored to allow of the free escape of water. On the top of the crocks 2 inches of drainage should be placed: this may consist of a layer of rough lumpy peat, interspersed with charcoal broken smaller. The box may then be filled up to within 4 inches of the top, with a compost consisting of two parts good fibrous peat, one part turfy loam, and half a part each of rough silver sand or river sand, and charcoal broken small.

The plants should then be turned out of the pots, and most of the old compost broken away, carefully disentangling the roots, and spreading them out over the new materials in the box, covering them afterwards with 1 to 2 inches of the same, pressing it moderately firm to fix the roots, and then giving all a good watering. Wires stretched under the roof at about 8 inches from the glass, and 6 to 8 inches apart, are best for training the young growths upon. They will require frequent attention during the growing season, which is principally from March until the end of July, and during which time and until the end of September too much water can scarcely be given to the roots, if planted and arranged as I have above directed. I give a very liberal supply every day during this period. From October until February I do not give water more than twice, and in dull weather only once, a week.

Frequent syringing of the foliage is not beneficial to the plant, but a thorough washing with the syringe or hose pipe occasionally on a summer evening is of benefit in clearing any dust, dirt, and insect pests. The north end or side of a house, where the direct rays of the midday sun do not strike upon the plant, suits it best, though it is not very particular upon this point, providing it is suited in other respects. Abundance of free ventilation should be given both day and night during hot weather, and above all, never forget in such weather its daily supply of water, to which may be added occasionally, providing the plant is healthy, weak liquid manure.

The most troublesome enemies of the *Lapageria* are the common aphid or green fly, with grey and black snails and slugs. The former appears to be very fond of the young and tender growths, and must be kept down by fumigation. The latter, which eat the young succulent stems as thrown up from the base of the plant, must be carefully watched for and hunted up at night when they are feeding at, say, from nine to ten o'clock. If trace of them is seen during the day it is a good plan to lay down a little dry bran, which seems very attractive to them, and near which they will almost certainly be found if looked for at the time I have stated.

The plant when in good health is a most profuse bloomer, and plants treated as I have above described are during the months of August, September, and October a dense sheet of bloom, and from thence onwards all throughout the winter a continuous supply of flowers, more or less abundant, is produced; indeed, scarcely at any period of the year are the plants entirely without blooms, which we find at all times useful for many different purposes. For the filling of *epèrnes* they are very effective, either cut with foliage and a portion of stem and allowed to droop over the edges, or cut without either foliage or stem, which is usually more convenient, and inserted in the dish heel downwards amongst plenty of *Lycopodium* or *Maidenhair Fern* fronds. They are also very effective in wreaths and crosses, for which purpose we cut them without foliage, and wire each flower separately; also for bouquets and for sprays of flowers for ladies' wear we find them to be much appreciated. In fact, where choice cut flowers are

much in request I do not know any other greenhouse plant equally valuable for so long a period of time.

I have not said anything as to pruning, for the reason that none is required unless the growths become unduly crowded, in which case the weaker ones should be thinned out. Propagation is effected either by seed sown in a gentle heat, or by layering some of the growths in such a manner that the stem and a portion of each leaf is buried in the compost. This, however, is a very slow and, in the case of amateurs, an uncertain business, so that it is best to go to a nurseryman for the plants required.

After the box becomes fairly well filled with roots and the plants are established, a top-dressing annually in April of fresh compost prepared as above, with a slight dash of Beeson's manure added, will be found to benefit the plants. A little of the old surface mould should at the same time be loosened and taken off carefully in such a way as not to damage the roots. In the hot sunny weather of summer I paint the glass on the outside with a coating of "Summer Cloud," which I find to be a very useful shading, and one not readily washed away by slight showers.—K. W.

EARLY PEAS.

THE mildness of the present winter seems likely to give us an exceptionally early spring, and those who have followed the time-honoured practice of sowing a few early Peas in December will, perhaps, make a "lucky hit," unless our treacherous climate once more deceives us during the next two months.

The practice of sowing an early supply in pots, or turves, placed in cool houses or pits, and planting them out in February as soon as the weather is favourable, is without doubt a good one; in fact I know of no other plan by which such early and satisfactory crops can be obtained in the open air. When this plan is adopted the young plants should be protected by means of Spruce branches, or other evergreens, as soon as they are planted in the open air, as our climate is too changeable to trust to chance in such a matter; and if they receive a thorough check through frost they seldom come into bearing much, if any, earlier than plants raised from seed sown in the open air.

Towards the end of January is a capital time in a season like the present one to sow early Peas on a warm border. If the ground has been already dug, I like to sprinkle a coating of newly slaked lime upon the surface, and during a bright day fork the soil over again to help it to dry quickly. If this is done before noon, in a couple of hours the soil will often be dry enough for drawing the drills. In most gardens a warm border is at command for the early crop of Peas, and as such borders are not often of great width the drills can be drawn 3 inches in depth, without scarcely treading upon the border; a matter of considerable importance in early spring.

When Peas have to be sown in heavy land no useful purpose is served by doing so before the soil is fairly dry, for to stir it about while it is "sticky" causes it to become more stubborn still. A little old potting soil, wood ashes, or even leaf soil, placed along the drills, the seed also being covered with the same material, helps greatly to forward growth after germination has taken place, and as early Peas are an important crop in private gardens those who have a stubborn soil to deal with will find this little attention is well repaid.

In regard to the distance apart at which the rows should be placed, a safe rule to follow is to allow as much space between as the height the haulms usually reach. Spinach, Lettuce, or Cauliflower can then be grown between, and one has the satisfaction of knowing that the most is made of the land by such a method of cropping. It is not a good plan to sow early Peas too thinly, as mice and birds often do much damage; on the other hand, it is a mistake to scatter the Peas along the rows thickly enough to touch each other. If placed about an inch apart the distance will be found generally suitable, but strong growing midseason varieties should be allowed double that amount of space.

A pair of very early varieties which it would be hard to beat are Carter's Lightning and Chelsea Gem. Early Eight Weeks is said by some to come into bearing a few days sooner than the two first named sorts, but as I have not grown them side by side I cannot vouch for the accuracy of the statement. Both English Wonder and American Wonder follow Lightning closely. The Sutton's Forcing is a great acquisition, being quite dwarf, and I think one of the very earliest Marrowfat Peas in existence. Our old friend, William Hurst, is also fairly early and a grand cropper, bearing fine pods. Among the taller growing early varieties Sutton's Early Giant, Dicksons' First and Best, and Veitch's Selected Extra Early are each of well-proved excellence.

Both mice and birds are foes which must be looked sharply after.

Coating the Peas in red lead before sowing may in some cases prevent mice from interfering with them, but it does not always do so. The only safe plan is to set traps and catch them. I have tried many plans for keeping birds at bay, and the most effectual one I have yet discovered is to fasten several lines of black cotton over each row, a few inches above the soil. The black cotton seems to answer better than white, as birds do not appear to notice it till their wings became entangled, then they are quickly frightened away. Strips of red cloth tied to sticks or strings a few feet above the soil scare the majority of birds for a time.

As soon as the young Peas are an inch above the ground I like to earth and stake, but I think early crops are not benefited by being mulched, as it helps to keep the soil cool at a time when it often needs warming. Without the mulch the hoe can be kept going close up to the plants, so that the warm air carrying both heat and nitrogen may be forced into the loosened soil, causing the roots to grow apace, and the living organisms (which the lumps on roots contain) to extract the nitrogen, and form it into such compounds as all leguminous plants can absorb.—H. D.

GLOXINIAS.

EARLY sowing of the seeds of Gloxinias will result in securing specimens that will bloom freely the first season. This is a distinct advantage, for the whole of the plants from a sowing may be flowered, retaining the best, and throwing away varieties that are inferior. If the best seed only is obtained there will be few of the latter. Any seedlings, however, which do not flower the first season should be kept growing in a suitable temperature, when they will flower early in spring, and perhaps give blooms of more than ordinary quality, for it is not always the seedlings that grow the quickest that are the best. Hence it is that every seedling should be cultivated to at least the flowering stage, whether that happen the first year or the second.

As the present is a suitable time to sow seeds of Gloxinias, a few details of the operation may be acceptable to those who have at command a temperature of 70° to 75°. A propagating frame in a plant stove is the most suitable position. Hot-water pipes should run under the frame, and moisture may be maintained in it by a good depth of fresh cocoa-nut fibre refuse. Heat and moisture are indispensable to the germination of the seed, as well as to carry on subsequently a steady and progressive growth.

The preparation of the compost and the receptacles for sowing in are important. Six-inch pots or wide shallow pans may be employed. They must be clean and dry, though if new they will be of such a porous character that moisture from the soil will be freely abstracted to the detriment of the seedlings, probably at a critical stage of their existence. To avoid this soak the pots or pans, that have never been used, in water for some hours, and after they are properly dry on the surface, inside and out, they are ready for use. Fill them about one-third with clean potsherds, the largest pieces at the bottom, the smallest on the top, covering the whole with a layer of damp sphagnum moss or fibre from the compost.

Fibrous peat and leaf soil in equal parts, with a little loam, plenty of silver sand, and a portion of finely broken charcoal, form a porous and suitable mixture. See that the whole is properly moist, which consists in being neither wet nor dry. Place in the pot or pans, pressing down fairly firm to within an inch of the rim, making quite level on the surface. Give a gentle watering with warm water through a fine-rosed can. When drained the seed may be sown, scattering thinly on the surface, just whitening it with fine sand. Great care must be exercised, as the seed is very small. It is not absolutely essential to cover the seed, though if it is done a mere dusting with soil or sand through a hair sieve will suffice.

Plunge the pots or pans to half their depth in the moist fibre. Cover with a pane of glass, and darken with moss or paper until the seed germinates. Then remove and admit air gradually. Let the seedlings have all the light possible, but maintain a regular brisk temperature and adequate humidity. As the seedlings advance in size they will require increased light and air. The general temperature and atmosphere of the stove will by this time have become suitable, and the pots or pans may be accommodated on a shelf near the glass in the warmest part of the structure. Shade when necessary from bright sunshine. Water must be given of the same temperature as the house, or a little warmer, by placing the pots or pans in the water so that moisture may percolate upwards by capillary action. The seed pots, however, should be taken out of the vessel of water as soon as the first signs of moisture appear through the surface.

Transplanting of the seedlings may be commenced when the most forward have attained a sufficient size. This is easily effected by means of a small flat stick, notched at the point, so that the little plants can be readily lifted without injury, and transferred to the

surface of prepared compost in other pots or pans, about an inch apart. Water but lightly, and keep rather closer and shaded for a short time, then assign the plants a warm position near the glass. The next move must be to 3-inch pots, and after that to 5-inch pots, in which the plants will grow to a good size, having large leaves and a quantity of flowers. When in flower in summer the plants do well in an ordinary greenhouse. The compost for the final pottings may consist of equal parts loam, peat, and leaf soil, with a little decayed cow manure, sand, and charcoal.—E. D. S.

DISCURSIVE NOTES AND QUESTIONS.

TEN MINUTES' JOTTINGS.

OCCASIONS may often arise for penning short notes of an instructive, suggestive, or inquiring character on different subjects when anything like a lengthy article could not be written on a particular subject. Moreover, I am inclined to think that a series of variety notes may not be less interesting, while easier to produce, than an elaborate essay. A few useful points of practice may be embodied in a few lines; questions may elicit information, and suggestions are never lost when recorded. I send a trio of ten minutes' jottings:—

CINERARIA PESTS.

I should be glad to know if there is a more radical cure for the ravages of the "leaf miner" or larvæ of the Celery fly (*Tephritis onopordinis*) than by hand manipulation. For some years I was luckily free from the pest, but recently it has been most troublesome, completely spoiling the appearance of Cinerarias by the mole-like burrowing in the leaves. I should like more testimony to convince me that plants unfed by artificial manures are the more severely attacked. I have noticed this on more than one occasion, and it leads me to think that the larvæ are not so partial to the tissues highly impregnated by the constant use of organic manure. Might we not anticipate in the future that by the skill of some experimentalist a chemical combination will be produced that, while acting as a manure, would fortify the plants against this destructive leaf miner? Singularly enough my next-door neighbour is never troubled with the pest, while I am much pestered, the plants in each case being grown under apparently the same conditions. Who can solve the problem?

SQUIRRELS *versus* WALNUTS.

Having several large Walnut trees within easy distance of the shrubberies and flower beds, and seeing occasionally at this time of the year the squirrels making various excursions thither, led me to watch their movements. After sundry scratchings in different parts of the beds they would find their hoard and make off to a neighbouring tree to enjoy their meal. Two things struck me as worthy of emulation, and as lessons which we ourselves might benefit by in our walk through life; first, the industry of these nimble-footed creatures. When their harvest is ready they are not allowed to be disturbed here, so that quite an army of them congregate. Silently, and with surprising quickness, do they collect the nuts one by one, and disappear for a few moments, returning again and again until all were "gathered in." I have come to the conclusion that these wise creatures bury their spoil singly in most cases in the ground. But why singly? Because of enemies, which if the nuts were stored in one heap might find their storehouse and empty it—a circumstance which could not happen in the former instance. Are the squirrels guided by smell or instinct in finding the solitary nuts? They do not seem to know the exact whereabouts of their hoard right away. One can understand the labour and exertion necessary to enable them to so store away their winter sustenance so securely. When in the heyday of abundance of good things there is no undue feasting and merrymaking, but one and all seem bent on securing as good a store as possible, putting by for the rainy day so sure to come. An all-wise Providence gives to these lowly animals the instinct to provide for their future well-being; surely it behoves all of us to imitate it in as large a measure as our means allow, bearing in mind the old maxim, "Heaven helps those who help themselves."

FLUED GARDEN WALLS.

It would be interesting to know whether there are still any of these now generally obsolete arrangements in use at the present time. They were in full swing here over forty years ago, but now only the double fire hole doors remain as outward evidence of the practice at that period. The oldest men can refer to the time when over each of these flue doors, which are situated about 20 yards apart, were roofs, and these, with the chimney pots on the walls, would, I imagine, give one the idea of a fort garrisoned with soldiers on the look-out for an enemy, rather than merely an artificially heated fruit wall. We still have in use a few of the blind poles, also some of the oak slabs, fashioned like a capital L, for gripping the 3 feet 3-inch wide coping stones, with a pulley at one end for the cords to go through, to draw the blinds up or down. The flues are made oblique or slanting. I should think the wall in the line of the flue would be very warm as compared with that part more isolated. It is difficult to see the utility of all this expense, with the attendant cost of firing. I believe there were fourteen double sets at work here in their owner, Sir Robert Heron's time. Are there gardeners still alive who can give us their personal experiences of the working of these ancient flues in garden walls?—GEO. DYKE, *Stubton Gardens, Newark.*

WEATHER IN LONDON.—On Thursday morning a very heavy fog enveloped the West-end of London, impeding traffic to a considerable extent, but towards the evening it cleared. Friday and Saturday were both fine, though not bright, while on Sunday it was slightly foggy throughout the day. No rain fell in the latter half of the past week, neither was there any frost. Monday was foggy throughout the day, but Tuesday was clear and bright.

WEATHER IN THE NORTH.—During the past week, with the exception of the 12th, the weather has been almost uniformly dull. Westerly winds have been frequent, and the temperature has been unseasonably high, 44° during the night recurring. Tuesday morning was gusty and wet. Snowdrops are getting into bloom, Crocus and Daffodils well above ground, and Roses show shoots over an inch in length.—B. D., *S. Perthshire*.

ROYAL HORTICULTURAL SOCIETY.—SCIENTIFIC COMMITTEE.—At the meeting on January 11th there were present Mr. Michael (in the chair), Dr. Müller, Dr. Russell, Rev. W. Wilks, and the Rev. Prof. Henslow, Hon. Sec. The minutes of the last meeting were read and confirmed. *Fungus on Beech.*—A box of fungi was received from Lady Cave, Cleve Hall, Downend, near Bristol. They were forwarded to Kew, whence it was reported that they were *Pleurotus ostreatus*, Jacq., "one of the best and safest of edible fungi." The specimens were taken from a very old Beech in the gardens of Cleve Hall. They were growing on the wood about 12 feet from the ground.

ROYAL HORTICULTURAL SOCIETY.—THE COUNCIL.—We observe from the balloting paper just issued that the three retiring members this year, in accordance with the bye-laws, are Messrs. Norman C. Cookson, James Douglas, and Thomas Gabriel. The Fellows recommended to fill the vacancies thus created are Sir Frederick Wigan, Bart., Mr. J. Gurney Fowler, and Mr. James Hudson. As the gardeners' representative Mr. Douglas has proved a very useful member, but he is now a commercial florist, and we have not a doubt that Mr. Hudson will prove himself an equally worthy representative of the craft that he adorns. We congratulate him on his nomination, which is no doubt tantamount to election to the honourable board. We may perhaps add that the chief bye-law, which governs the retirements and elections, is the following:—"At every annual meeting of the Society three members of the Council shall be removed by ballot of the Fellows present, and the vacancies so created shall be filled up by the election by ballot of the Fellows present of three other discreet Fellows of the Society." The annual meeting is to be held on February 8th.

R.H.S. FINANCES.—It is gratifying to notice that the total income of the Society during the past year amounted to £6303 13s. 7d., also that there is a balance over expenditure (£5481 6s. 3d.) of £822 7s. 4d. The deaths of Fellows in 1897 numbered fifty-three, the resignations fifty; together involving a loss of £134 8s. As compensation we find that 428 Fellows were elected during the year, equivalent to a gain of £551 15s. 6d.; after deducting the above loss there is a net increase in income of £417 7s. 6d.; numerical increase of Fellows, after deducting the loss of 102 above mentioned, 325. Thus the Society is in a thoroughly sound state—a state moreover of increasing prosperity, for we believe the election of new Fellows at the last meeting was unusually large, and thus indicative of another prosperous year.

THE CULTURE OF VEGETABLES AND FLOWERS FROM SEEDS AND ROOTS.—The continued demand for this admirable work of Messrs. Sutton & Sons is the best possible proof of its acceptability. The seventh edition is before us, and from whatever point of view regarded, excellence in production, variety in subjects treated, soundness of information, or attractiveness and instructiveness of the illustrations of insects and fungi, we are bound to speak of it in terms of the highest praise. The cultural requirements of all kinds of garden vegetables, also of flowers raised from seeds and roots, are clearly set forth, and the same may be said with regard to the formation and management of lawns and tennis grounds. The work may be fairly described as a safe gardener's guide and trustworthy amateur's friend, and neither one nor the other will err by following the advice contained in its 418 pages, plus an excellent index.

ROYAL GARDENERS' ORPHAN FUND.—We have the pleasure to announce that C. E. Keyser, Esq., Aldermaston Court, Reading, will preside at the annual festival dinner of the Royal Gardeners' Orphan Fund on Wednesday, the 20th April next, at the Hotel Metropole.

RAINFALL AT OLD WARDEN PARK, BIGGLESWADE, IN 1897.—Mr. G. R. Allis writes:—"The rainfall as registered here during 1897 amounted to 27.09 inches; rain fell on 137 days, and snow on five days. March was the wettest month, when rain, 3.41 inches, fell on twenty days. July was the driest month, 0.34 inch. The rainfall for 1895 and 1896 amounted to 25.86 and 25.7 inches respectively."

"PROFESSIONAL."—At an inquiry held at Lambeth the other day, a witness described himself as a professional gardener. The Coroner: All men in your business call themselves professionals, don't they? Witness: There is a vast difference between professional and ordinary gardeners. I am competent to give a lecture on botany and horticulture. The Coroner: Then ordinary gardeners only scrape the weeds up, I suppose? (Laughter.)

DEATH OF SIR JOSEPH TERRY.—Last week we (on page 33) briefly reported the proceedings of the annual meeting of the guarantors and life members of the Grand Yorkshire Gala as presided over by Sir Joseph Terry, who was at the same meeting unanimously elected Chairman of the Council for the current year. It is with deep regret that we find the death of Sir Joseph occurred suddenly when our report of the meeting was in the press. The deceased gentleman, who had been thrice Lord Mayor of York, was an active worker in the interests of the Gala and flower shows, and a warm welcome was always accorded him when presiding at the Judges' luncheon. In his quiet, happy way he made all happy around him, and by his innate urbanity and geniality won the esteem of all classes. He was held in great favour by horticulturists who visited the shows from year to year, and his loss will be much lamented. The deceased gentleman was seventy years of age.

THE ROYAL BOTANIC SOCIETY.—At the meeting of the Fellows of this Society on Saturday, Major Cotton, who presided, referred at some length to the present position of the Society. In the course of his observations, he stated that the year 1897 had been a very eventful one in the history of the Society, and he was pleased to be able to congratulate the Fellows upon the very excellent position in which the Society now stood as compared with its position at the opening of last year. The unsatisfactory position had been resolutely faced, and he was pleased to say that, with the co-operation of the Council and some of the leading Fellows, the Society was now perfectly solvent, and the accumulated debt which had so long been a source of trouble and anxiety, had been swept away. A new lease for the maximum term of thirty-one years had been promised by the Commissioners of Woods and Forests, and it now only remained for the Fellows to use their utmost endeavours and to induce friends to make the Society the success it should be. Not only were the gardens open for study to the pupils of the various medical schools, but a school of practical gardening had been started with the concurrence and aid of the London County Council. Reference was made to the great increase in the numbers of Fellows elected in 1897, there having been more than eighty above the average numbers of the last ten years.

GRAPES.—The new Grape Directeur Tisserand, recently receiving an award of merit, and which was again placed before the Fruit Committee on the 11th inst., whilst exceedingly nice, yet showed that it would not keep long, as the berries had begun to shrivel. It was felt under the circumstances that any higher award would not be justified. It would have, of course, been useful to have learnt how early or otherwise the Vine carrying the fruit was started into growth. Compared with the fine and perfect berries seen on Mr. J. Bury's Colmans and Alicantes those of the new Grape were too advanced. Still, it is very difficult to pronounce an exact verdict until the Grape has been more widely grown. The Alicante sport staged by Mr. Rochford presents features of great interest. The bunch shown indicated free setting, a Gros Colman berry, although rather more oval, and an Alicante skin. Well finished, which the sample sent was not, it should hang very late. This seems to be a pure sport, and at present is growing on a rod which carried below the sport union fine bunches of Alicante. The sport had produced several bunches. Judging by the indifferently coloured sample seen it would appear to need a long season like Gros Colman. When it is propagated, as perhaps it already is, and has fruited on its own roots, then its real character will be seen. The present inference is that it will develop into a most valuable late-keeping Grape. Mr. Bury's collection of Grapes, apart from their table value, very markedly helped to show how Grapes may be marketed in the best possible condition in the now well-known cross-handle baskets.—A. D.

— **FLAX AND HEMP.**—We find from the prospectus of the English Fibre Industries, Limited, of which Mr. Chas. T. Druery is the Secretary, that, despite the enormous home consumption of both staples, raw and manufactured, our country has practically been entirely dependent for its supplies upon outside sources, importing Flax and Hemp to the annual value of about four and a quarter millions sterling, and Linseed to over three and a quarter millions in addition. "At present the Company is converting raw Flax into fibre and selling the same," and evidently wants to do sundry other things for fostering home industry and making money.

— **KNIPHOFIA PRIMULINA.**—Several plants of this charming species are now to be seen in flower in the temperate house at Kew. Through its lateness of flowering it has been found to be of little use for outside work, but grown in pots and stood in a cold frame on the approach of winter, it is found to make a very acceptable addition to the greenhouse after Chrysanthemums are over. It adapts itself readily to this mode of culture, growing strongly and flowering freely, plants in 8-inch pots producing three or more spikes of flowers of a pale yellow colour. As it can be grown outside until the spikes begin to show, and can be put outside again at the end of March, it will stand with feeding several years in the same pot. It is bound to be, as it becomes better known, one of the most popular winter-flowering greenhouse plants. If any plants are not showing flower at the end of November, and there is no frame room for them, they should be plunged deeply in dry leaves, this being the best protection against frost.—W. D.

— **HIMALAYAN RHODODENDRONS.**—The members of the Devon and Exeter Gardeners' Association were much interested recently, at the Guildhall, Exeter, in a paper prepared by Mr. Richard Gill of Penryn, Cornwall, on the subject of Rhododendrons. The introduction of many of the tenderer forms instituted a new era in outdoor cultivation. In the West of England and South Wales, in addition to the mildness of the climate, the humidity of the atmosphere greatly favoured the Rhododendron. They were great lovers of peat in some form or other. Granite sand, in the proportion of one-third, might be added with good results. The plants did not like a lime or chalky soil, or a stiff water-logged clay. Being surface-rooting plants, they would not stand prolonged droughts, but care must be taken to prevent the accumulation of stagnant water round the roots. The lowest branches of the Rhododendron should be carefully preserved and encouraged, as they kept the soil around the roots comparatively moist in the driest season.

— **KENSINGTON PALACE.**—Relative to the opening of the State rooms of this historic place to the public by the Queen, a daily paper remarks that the beautiful banqueting room of Wren's is used as a potting shed; and also goes on to say that some idea of the gardens in the time of William and Anne may be had from the following description. In those days the Dutch taste, of course was predominant—evergreens were transformed into shapes of birds, beasts, and monsters; slopes, labyrinths, trees trimmed into gigantic dumb-waiters; long alleys of alternate Box and Apple trees, with obelisks peeping between every other tree. "To crown these impotent displays of false taste," says one writer, "the shears were applied to the lovely wildness of form with which Nature has distinguished each various species of tree and shrub. The venerable Oak, the romantic Beech, the useful Elm, even the aspiring circuit of the Lime, the regular round of the Chestnut, and the almost moulded Orange tree, were corrected by such fantastic admirers of symmetry."

— **SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES.**—The ninth annual dinner of this flourishing Society was held on Saturday evening last, the 15th inst., when Mr. Herbert Cutbush occupied the chair. The gathering was well attended, and the proceedings were of the heartiest nature. Amongst the visitors representing English horticulture were Mr. H. J. Jones, Mr. Wm. Cutbush, Mr. Harman Payne, Mr. Harry Laing, Mr. J. Weathers, and several more. Dinner being over, the President of the Society, Mr. George Schneider, formally introduced the Chairman, who, in an excellent speech, reviewed the progress of the Society. Mr. Schneider, in reply, thanked the members for the spirit of comradeship that always animated them. He also attributed a large measure of the success of the Society to English friends. At this point a little surprise was in store for Mr. Schneider as Mr. Gachlein arose to make him a presentation of a case of cutlery and an address on behalf of the new members. Mr. Schneider appropriately replied to this unexpected demonstration of good feeling towards him, and as a close to the proceedings, the company very heartily sang the English and French National Anthems. Messrs. Cutbush & Sons of Highgate received a cordial vote of thanks for the floral decorations.

— **RICHMOND HORTICULTURAL SOCIETY.**—We are informed that the summer show of this Society has been fixed for Wednesday, June 29th.

— **MILD WEATHER IN ARGYLLSHIRE.**—Mr. Thos. W. Pritchard, Glenborrodale Castle Gardens, Ardgour, writes:—"The weather in this district is very mild. We have Primroses and Rhododendrons in full flower, and have not registered frost since October, 1897, then we had only 3°."

— **A GARDENERS' ASSOCIATION'S ALMANACK.**—We have received a large sheet almanack, 25 by 20 inches, prepared by the Isle of Wight Horticultural Association. It is an excellent example of its kind, appropriate and useful. It contains a list of the officers of the Society, honorary members, and gardener members, as well as the dates of shows of the eighteen horticultural societies in the Island; a selection of books for gardeners to read; tables of planting, distances, and the longevity of vegetable seeds; dates of the R.H.S. and the N.C.S. meetings; also a good calendar of gardening operations. It is the first sheet of the kind we have seen as issued by a gardeners' association, and is a highly creditable production.

— **WINTER VEGETABLES.**—What a remarkable season for all descriptions have we had so far, and how cheap and plentiful they have been. If market growers have not obtained high prices, and the day for those in connection with hardy vegetables seems to have gone absolutely, at least they have had plenty of material to market, and gathering has been very easy. Probably the chief loss, so far as there has been any, has laid with Savoy Cabbages, for whilst these have been forced by the mild weather into hearting early and universally, they have been little in demand. Mild weather favours Cauliflowers, which have been wonderfully abundant; early Broccoli, Brussels Sprouts, and Coleworts, and when these Brassicæ are plentiful Savoy are little called for. The Savoy, too, is essentially a hard weather Cabbage, but so far with Savoy white in heart, in vast quantities, the hard frosts have been absent. No doubt market growers would plant few or many of these Savoy could they foresee mild or hard winters. Yet the Savoy planted much later than usual, that it might heart in small and green in March, might prove to be a most profitable Cabbage crop. Next to the "Whiteheads," the long-enduring Brussels Sprouts hold the field for popularity with the general public. Coleworts and early White Cabbages come next. The real pinch is found in April and May, when all ordinary winter stuff being over, very late Sprouts, early spring Cabbages, and Spinach are the chief hardy products. How very valuable just then is a good stock of Seekale for blanching. Hardy as is this product, easily grown, and most profitable, still the day seems far distant when it can ever become a cheap people's winter vegetable.—D.

— **READING GARDENERS' ASSOCIATION.**—The annual general meeting of the Reading and District Gardeners' Mutual Improvement Association was held recently, Mr. C. B. Stevens presiding over a good attendance of members. The report and balance-sheet, read by the Hon. Secretary, Mr. James Pound, jun., were of a very satisfactory nature, both showing that the Association was in a very flourishing condition. The membership was still on the increase; thirty-one new members had been elected during the year 1897, making over 180 "paid up" members on the books, whilst the balance in hand was double that at the end of 1896. The Committee regretted the death of Mr. Alfred Sutton, who had always taken a great interest in the work of the Association, and had since its formation in 1888 provided the club-room for their meetings. They also record the death of Mr. George Palmer, who was an annual subscriber from the commencement of the Association. The meetings during the year had been well attended, on some occasions upwards of eighty members being present. The thanks of the Committee were due to the President, Mr. C. B. Stevens, for the great interest shown not only in presiding at their meetings, but taking an active part in all the other business connected with the Association; to Messrs. Sutton & Sons for their kindness in providing a room at the Abbey Hall for the use of the members, and supplying it with horticultural and other literature; to the honorary members for their kind and general support; to those who have helped forward the work by reading papers and introducing subjects for discussion; to those who have added so much interest to the meetings by bringing exhibits of flowers, and to the horticultural and local press for publishing reports of the meetings. A beautiful group of well-grown Cyclamens was shown by Mr. W. Townsend, The Gardens, Sandhurst Lodge, noticeable being Sutton's Butterfly, Vulcan, Salmon Green, and Giant White varieties.

— **THE HAMBURG INTERNATIONAL HORTICULTURAL EXPOSITION.**—We observe that this exhibition, which closed at the beginning of October, resulted in a surplus of 300,000 marks. The amount received from season tickets was 810,000 marks, and from daily tickets 770,000. The receipts for rentals of dining halls and sale of privileges was enormous. This shows the interest which the German people take in horticultural matters.

— **MARRIAGE OF MR. BERNARD COWAN.**—The marriage of Mr. Bernard Cowan, Harton Cemetery, with the widow of the late Mr. Peter Marshall of South Shields, which took place on the 13th ult., may be matter of interest to many readers. Mr. Cowan is a lecturer on horticulture for the Durham County Council. He was the first Chairman of the Newcastle and District Horticultural Mutual Improvement Association, and is one of the Vice-Presidents of the English Arboricultural Society. He is also Secretary of the South Shields and Northern Counties Chrysanthemum Society.

— **ANCIENT SOCIETY OF YORK FLORISTS.**—The annual meeting of the above Society was held on the 11th inst., Mr. Councillor J. E. Wilkinson in the chair. There was a good attendance. The Secretary (Mr. John Lazenby) read the report and balance-sheet. The report showed that the year's work had been very satisfactory. Financially, it was satisfactory to note that at the close of the year there was a balance in hand of £180 11s. 11d., as against £177 17s. 1d. last year. Mr. Lazenby writes:—"A most regrettable circumstance happened to us in the death of our beloved President, Alderman Sir Joseph Terry, within a few hours of his re-election." A sum of £70 was allotted for the minor or summer free shows, and £170 to Chrysanthemum show, this year, apart from many special prizes offered.

— **"THE GARDEN AND FOREST."**—It is a matter for regret to learn that this admirably conducted journal has ceased to exist. For years it has been considered one of the best managed and most reliable of the American gardening papers, and many readers will miss it. In announcing their decision the conductors say, "With the present issue, which completes the tenth volume, the publication of 'Garden and Forest' ends. For ten years the experiment has been tried of publishing a weekly journal devoted to horticulture and forestry, absolutely free from all trade influences, and as good as it has been possible for us to make it. This experiment, which has cost a large amount of time and money, has shown conclusively that there are not persons enough in the United States interested in the subjects which have been presented in the columns of 'Garden and Forest' to make a journal of its class and character self-supporting. It is useless to expend more time and money on a publication which cannot be made financially successful, and must, therefore, sooner or later cease to exist."

— **THE WEATHER.**—It is not wise to holloa before you are out of the wood, nor to cry out summer when winter is not half over. Only three years ago one of the hardest frosts of the century occurred as late as February. But so far as the winter has gone it has undoubtedly been one of the mildest we have had for many years past. With the exception of three or four days about Christmas time there has been no frost to speak of in any part of England. In London the thermometer on no fewer than thirteen out of the past forty-three days has risen in the daytime to 50° or more, and on two consecutive days in the middle of last month it went above 55°. On four days only has the thermometer failed to touch 40°, and on the coldest of these it rose to 37°. Frost has occurred in the screen on as many as fourteen nights out of the forty-three, but with the exception of five occasions ending with Boxing morning, it has never prevailed for more than two nights in succession, and has never been of any great severity. Neither snow nor sleet has been seen in London. This is a state of things without parallel in the winters of the past five-and-twenty years. In the winter of 1888-89 snow did not put in an appearance in London until the 12th January, but with this exception a fall of greater or less severity occurred in every December of the past twenty-five years, in thirteen Novembers, and even in six Octobers. The prevalence of fog in London this winter has been generally looked upon as far in excess of the average. Taking, however, the number of days only on which it has occurred, irrespective of density or length of continuance, there have been other winters of recent years equally ill-favoured, among them being the seasons of 1891-92 and of 1892-93. If, however, we have had more fog than is our due, we have certainly been favoured with an unusual amount of bright sunshine. At Greenwich the total duration last month was no less than fifty hours, being as many as fourteen hours in excess of anything recorded there in December since the sunshine instrument was set up in 1876.—("Daily News.")

— **DEATH OF MR. MAX DEEGEN.**—We regret to have to record the recent demise at the age of fifty-six years of this well-known Dahlia grower. The death occurred at Köstritz, in Thuringia. For many years he has been known as one of the most successful raisers of new Dahlias, and English, with foreign growers, will feel the loss.

— **DEATH OF MR. M. LAURENCE.**—Many persons will deplore the death of Mr. Michael Laurence, who since 1847 has had charge of the flower gardens at Tostock House, Suffolk, the seat of Mrs. William Gilbert Tuck. Although more than eighty-two years of age, he remained active until the last, and was rarely absent from his work.

— **ISLE OF WIGHT ASSOCIATION.**—The annual meeting of the Chrysanthemum Society was held at Newport on the 15th inst. Dr. J. Groves, B.A., J.P., presided over a large attendance of members and exhibitors. The report and balance-sheet were unanimously adopted on the motion of the Chairman, who regretted that the balance in hand was less than last year—£18, against £22 last year. The question of an Isle of Wight championship prize was brought forward and delegated to a Sub-Committee, to discuss and report to the Society. Sir Chas. Seely, Bart., was re-elected President, Dr. J. Groves was re-elected Chairman, and Dr. Coombes re-elected Treasurer, and Mr. C. H. Cave Hon. Secretary.

— **PLANTING AND PRUNING.**—The second of the lectures organised by the Morden Cottage Garden and Industrial Society was given on Thursday last at the Village Club, Morden. The lecturer was Mr. C. Gibson, head gardener to J. Wormald, Esq., of Morden Park, and he took for his subject "Planting and Pruning." Touching lightly on the ordinary trees and evergreens, the details of various kinds of fruit trees were carefully gone into; their selection, planting, soil, mulching, and removal. The dangers of deep unskilful planting were pointed out, and hints given as to the best kind of fruit trees for a cottager to select, the most early and prolific, and the price which ought to be paid for them. The second half of the evening was devoted to pruning, and the interest was much heightened by specimens of trees pruned by different methods and not pruned at all; these were explained and experimented on, and the lecture closed with an interesting discussion.

— **CARNIVOROUS SLUGS.**—The observations made by Mr. Thomas Arnold (page 39) are exceedingly interesting, as but few records apparently exist in support of the statement that worm-eating slugs seize and swallow other slugs. I have heard of two *Testacellæ* being found with the opposite ends of the same worm in their mouths, but Mr. Arnold "goes one better," though he does not tell us which slug made the best meal. Judging from the drawing (fig. 7) the mollusc in question is *Testacella haliotideia*, though it might be the other small shelled species, *Testacella scutulum*. The latter is usually more yellow than the former, and the lines on its back meet in front of the shell, while in *T. haliotideia* they run together just under its edge. With regard to the larger shelled species, *T. Mangei* was evidently a misprint for *Maugei* (named after Mauge). The fact that it has now been found in most south-western counties of England, in Wales, and in Ireland, points to its being indigenous to this country. I should be pleased to hear anything my readers may know of white (albino) or black examples of these slugs, and to have any specimens they may be kind enough to send me, as I am still engaged in working out their distribution.—WILFRID MARK WEBB, *Ellerie, Brentwood.*

— **CROWN WOODS AND FORESTS.**—The report for the year ended 31st March, 1897, of the Commissioner in charge of the Crown woods and forests has been issued. The property under the direction of the Commissioner comprises the New Forest, Dean Forest, and the whole Crown property in Wales, county Monmouth, in Scotland, in Ireland, and in the Isles of Man and Alderney. The income derived from the New Forest from sales of forest produce amounted in the year 1896-7 to £7355 4s. 11d., and certain service rents, amounting in the same year to £3099 11s. 8d. The income derived from the Forest of Dean from the sources above mentioned amounted to £5305 17s. 7d., and £1856 12s. 11d. respectively. During the year there were about 660 acres added to the area enclosed for planting purposes. With a view to introduce in the Forest of Dean and the Highmeadow Woods a more scientific and systematic system of forest cultivation than has hitherto been adopted, the Commission has arranged with an experienced Conservator of Forests in the Indian Forest Service to make a detailed examination of the woods and furnish a report on them. It is desired not only to improve the prospective yield of the Forest, but also to establish such a system of management as may serve those who desire to study forestry in this country with a good practical object lesson, such as at the present time they have to go to France or Germany to find.

DEATH OF MR. J. LINDEN.

THE death is announced of one of the most celebrated of Belgian botanists and horticulturists, Mr. John Linden, of Brussels, which occurred on the 12th inst. In his early manhood Mr. Linden was one of the greatest of plant collectors, and he travelled for many years in search of novelties, more particularly Orchids, and it was his discovery of species growing at high elevations on the Cordilleras which demonstrated that many Orchids could be successfully grown in much lower temperatures than had hitherto been possible.

Mr. Linden eventually became Director of the Zoological Gardens at Brussels, and he established a nursery in the environs of that city. From there he went to Ghent, and for some time carried on an extensive business in the nursery formerly belonging to the late Mr. Ambroise Verschaffelt. Mr. Linden subsequently returned to Brussels and formed a company, of which his son, Mr. Lucien Linden, is the manager. This is, no doubt, one of the best arranged nurseries in Europe, and on our last visit we were much impressed by the systematic arrangement of the structures, and the orderliness and the cleanliness of the establishment throughout.

Mr. Linden was some years ago a formidable competitor at horticultural exhibitions, and one of his greatest contests was for the large gold medal of 500 francs at the Brussels Centennial in 1876, offered for a collection of twenty-five *Dracenas*, remarkable for their novelty, their culture, and their beauty. Mr. Linden probably exhibited the grandest plants ever seen at any exhibition, some of them 8 feet high, clothed with leaves to the base, some of them being 4 feet long; but the late Mr. C. F. Bause had just time to grow the then startling novelties which he had raised for the late Mr. John Wills, to exhibition size, and to these the Jury, after an hour's examination and consideration, awarded the medal. This was, perhaps, the most exciting contest we have witnessed. Mr. Linden's magnificent plants were overwhelmed by the "novelty" of those placed against him, while they were as well grown as plants could be of the age at which they were exhibited; yet, notwithstanding, Mr. Linden won the Queen's Prize of Honour, and may be described as the premier Belgian exhibitor at that memorable show.

He was a diligent worker in the domain of horticultural literature, of which the "Illustration Horticole" and the beautiful "Lindenia" afford abundant testimony, and his name is commemorated in many plants which are grown in gardens all over the civilised world. Mr. Linden was eighty years of age.

HARBINGERS OF SPRING.

THE mildness of the present winter has done a little to compensate for the more than usual amount of foggy and otherwise dull weather which has been experienced about London during the past two months. From the absence of severe frosts many spring flowers are now open which are usually a month or more later. At Kew, on January 9th, forty species of hardy plants were noted in flower, including shrubs, herbaceous and alpine, though, of course, were a few sharp frosty nights to come most of these would be injured.

It will, perhaps, be of interest to mention some of the most noteworthy of the plants referred to. Among shrubs a very attractive sight is a bed of *Hamamelis arborea*: the plants are about 9 feet high, and every branch is wreathed with bright golden blossoms. On a wall near by several plants are flowering, *Chimonanthus fragrans grandiflora* being particularly fine. There is also a specimen of the male *Garrya elliptica*, which is well worth growing both as an evergreen and flowering shrub; at present its long green catkins are the chief attraction.

In the arboretum several *Erieas* are flowering. The most showy is *E. mediterranea hybrida*. It is a dwarf growing plant, resembling *E. carnea* more than *E. mediterranea* in general habit, but taller and rather looser than that species. The flowers are red. Others worthy of notice are *E. carnea*, *carnea* var. *alba*, *mediterranea glauca*, and *E. m. lusitanica*, the latter probably better known under the name of *E. codonodes*. A few flowers are to be seen on *Rhododendron dauricum*, and *R. parvifolium* is nicely in flower. The latter is a Siberian and Northern Chinese species, with small rosy purple flowers; it has a loose scraggy habit, and is not a desirable plant for general cultivation. A few *Arbutus* flowers may still be seen on one or two species, though most of them are now over.

In several places about the grounds there are flowers of *Pyrus japonica*, and in numerous places *Jasminum nudiflorum* is covered with blossoms. *Loisericas Standishii* and *fragrantissima*, both covered with sweetly scented white flowers, look charming, as also does *Daphne Mezereum*. The Glastonbury Thorn, *Crategus oxyacantha praecox*, has been flowering off and on for the last two months, and will continue to open a few flowers for several weeks yet. *Berberis nepalense* looks bright with its large terminal heads of yellow blossoms, while *Viburnum Tinus* serves to enliven several shrubberies.

In the rockery several species of *Helleborus* are in flower, among them being *H. caucasicus*, *colchicus*, *odorus*, *antiquorum*, *orientalis roseum*, and *niger*. The latter species may also be seen flowering freely in several other parts of the gardens. Other plants in the rockery in flower are *Iberis sempervirens Garreuxiana*, *Arabis procurrens*, Snowdrops, and Primroses. *Crocus etruscus*, *Sieberi*, and *Imperati* are flowering in beds near the rockery, while at the foot of the wall between the herbaceous ground and rockery a mass of *Merendera caucasica* is very effective. At the foot of the Orchid house wall a row of *Iris stylosa* is producing

numerous flowers, and will continue to do so for several weeks. Although several other plants are in flower, those mentioned will be sufficient to show that the hardy plantsman can spend an enjoyable walk in Kew, even so early in the year as the beginning of January.—W. D.

LOS ALTOS, SANDOWN, ISLE OF WIGHT.

THIS is the residence of G. W. Drabble, Esq., and is beautifully situated on an eminence, which affords a magnificent inland view of the Island, from the noted Ventnor Downs (south) to Brading (north). To the west the true character of the Island is seen in the innumerable undulations and the adornment of hill and dale with giants of the forests, relieved with cosily situated farmsteads and pretty villages, which give the whole a picturesque appearance.

The gardens attached to Los Altos are ably managed by Mr. J. H. Perkin, a genial and most amiable gardener, who is ever to the fore in developing the horticultural interests of the Island. The vineries are up-to-date structures, and contain some healthy canes of Buckland Sweetwater, Black Alicante, Black Hamburg, Foster's Seedling, and West's St. Peter's, which have produced some fine bunches of Grapes. Tomatoes are splendidly managed, and this year the grower secured the Isle of Wight Horticultural Improvement Association's certificate for a fine dish of the variety Polegate.

The stoves contain a fine collection of table and decorative plants, which are in great request when the family is in residence. The Palm house, which is 40 feet long and 22 feet wide, was built in 1890, and contains some huge Palms, Tree Ferns, *Araucarias*, and *Dracenas*. The conservatory is a modern structure of about the same dimensions, and is admirably adapted for the preservation of flowering plants taken from the houses.

The fruit crops suffered more or less last season, with the result that small fruits, and Apples and Pears, have only been about the average, whilst Cherries and Plums were below the average. An extensive kitchen garden is well cropped. The beauty of the estate is undoubtedly enhanced by the magnificent specimens of *Coniferae* on the lawn and on both sides of a long carriage drive. The illustration (fig. 10), from a photograph by Mr. Alfred Drabble, conveys an excellent idea of the estate and of the Island.—S. HEATON.

CARDOONS.

THE Cardoon is more appreciated on the Continent than in England; but, nevertheless, it is met with in this country oftener than was the case some few years back. This serves to show that its merits as a winter vegetable, and as an agreeable change when choice is somewhat limited for the table, is gradually but surely coming to the front. When well blanched, properly cooked and served, Cardoons are not to be despised by any means, as they then make a palatable dish.

We do not require the produce for use before November, and therefore we do not sow the seed in pots. On the other hand, if good stout plants are required for August exhibitions, or very early autumn use, they should be sown in small pots in February, placing two seeds in each, and if both germinate reduce the number to one. Stand the pots in a vinery just started. When the plants are large enough transfer to 48-size pots, and put back in the same structure until the roots have taken to the fresh compost, when the plants may be removed to cooler quarters, and gradually hardened prior to being planted out towards the end of May.

Unless the soil is of a very tenacious character they are best grown in trenches, as prepared for Celery. If allowed to become dry at the roots the stems instead of being juicy and succulent will be hollow and pipey, and the plants will be only fit for the rubbish heap. We usually get out our trenches for Cardoons 8 feet from row to row, and crop between them with such vegetables as Spinach, Turnips, Lettuce, French Beans, or anything not likely to occupy the ground for any great length of time. Room should be left so that water can be given freely when needed.

After taking out the trenches 1 foot in depth, place about 6 inches of decayed manure in the bottom, cover over this 4 inches of fine soil, made firm by treading well. Early in April stretch the line down the centre of the trench and place three seeds every 2 feet apart, but at the final thinning allow only one plant to occupy each space. Should the weather be dry at the time of sowing a good watering will soon cause the seed to germinate, and as the young plants appear keep a sharp look out for slugs, or they will find their way to the tap root, and eat away the centre.

The prominent sharp spines on the leaves are not conducive to Cardoons becoming general favourites with gardeners, as tying them up for blanching is by no means a pleasant occupation. Hay bands form the best material for wrapping around the stems, after which soil must be added to keep the plants upright and secure from frost. Cardoons form imposing objects when used in subtropical bedding or as single plants in large borders.—C. FOSTER.

MARKET GARDENS, DENVER, COLORADO.

By way of preface, Denver is located at an altitude of 5196 feet. According to the observations of the United States Signal Service Bureau the average temperature is 49° (the average maximum being 79° and the average minimum 19°); the average annual rainfall or melted snow, 14.95 inches; the average number of days per annum on which snow or rain falls, 81; average number of sunny days, 340.

The Denver of the "sixties" was a struggling frontier settlement of less than 5000 people, 700 miles west of the nearest railroad. The Denver of to-day is a city of 165,000 people, with numerous seven, eight, and nine-storey business buildings and hotels, 150 miles of electric and cable street car lines, and the "hub" from which radiate over 26,000 miles of railroads, giving quick access to every part of the United States, and placing Denver within thirty-six hours of Chicago, fifty hours of New York, and ten days of London. In the early "sixties" a Denver man who had the temerity to attempt to raise Cabbages evoked much merriment. He succeeded, however, and sold his Cabbages readily at Central Africa prices, namely, from 50 cents (2s.) to 75 cents (3s.) per pound,

known. The rich sandy soil near Denver seems peculiarly adapted for it. A few years ago Celery from Michigan was considered the finest in America, but now takes second place to the Colorado product. Denver Celery commences to go to market early in August, long before Celery from any other point is fit to eat, and excels in being sweet, brittle, and succulent. Speaking from personal experience, it is infinitely superior to English grown Celery in appearance, crispness, and flavour, the Colorado growers producing a small, compact, white, and useable head, with the maximum of heart and the minimum of outside, as against the larger, coarser, and inferior head usual in England, and marketed there with tough, stringy, purple, red, or green outside stems.

The Celery is raised in hotbeds early in the spring, and by the time the ground is ready the seedlings are large enough to transplant into rows. Here they are irrigated and cultivated until grown with a good top, when the gardener prepares for bleaching. This is done by building a protection of boards for the lower part of the plant, in such a way that when completed the Celery looks as if it were in a trough. Only the tops are visible, the bottom part being concealed by the boards, held in place by stakes driven in the ground. When the stalk is bleached perfectly

FIG. 10.—LOS ALTOS, SANDOWN, ISLE OF WIGHT.

giving him the laugh on his neighbours. From that beginning, but chiefly during the last ten years, the vicinity of Denver, by means of artificial irrigation, has become a district of market gardens, brief particulars of which will interest your readers.

Four or five years ago a few vegetables were shipped from Denver by express—i.e., parcel company, but not until 1894 was any attempt made to ship mixed vegetables in carload lots. Since that time, however, the business has grown in a wonderful manner, until now the local market gardens not only supply Denver and many other parts of Colorado, particularly the mining districts, from 7000 to 11,000 feet altitude, but most of Texas, with considerable shipments to Arizona, Utah, Montana, Wyoming, and other States, where the summer heat is too great for successful gardening.

The first carload of Denver vegetables shipped to Texas proved such a success, that last year one whole train of fifteen refrigerator cars went to the principal towns of Texas, besides numerous other considerable shipments, and this season already eighty cars have been shipped, with a still greater number to follow. Be it remembered that these refrigerator cars have a capacity of 20 tons each. The list comprises Potatoes, Cabbages, Celery, Tomatoes, Turnips, Parsnips, and any other crops in season. The crops are frequently contracted for beforehand: say a given number of acres of Cabbages, of Celery, of Tomatoes, or other kinds, so that the gardener knows what to grow. Intense cultivation, and with suitable soil, heavy manuring, good cultivation and climate, heavy crops are the invariable result.

Colorado Celery already has a name for superiority wherever it is

white the Celery is dug, the roots trimmed off, and tied in bunches of a dozen heads to the bunch. It is then ready for the market. Last year hundreds of acres of Celery were grown under contract for export. This year the acreage will be doubled to supply the demand. A visit to the Celery farms along the Platte River will show some of the most prosperous people around Denver. The oldest Celery garden can boast of but eight years, yet the owner has a handsome brick house and one of the neatest and most comfortable homes in the valley. It seems a money-making business, but requires experience and careful work to make it successful.

As to other vegetables, it may be stated that one Denver factory has this season contracted for five hundred (500) acres of local Tomatoes at 9 dols., or about 37s. per ton delivered, the crop ranging from 10 to 15 tons to the acre. The growers have the privilege of selling all they can at the best prices they can to the wholesale and retail trade for fresh consumption, the factory taking the surplus at the above rate. Such factory has a force of considerably over 150 people in its canning department. The same concern has also purchased last season 30,000 bushels of locally grown small Cucumbers for pickling.

As to winter vegetables, one man in the outskirts of Denver has 20,000 square feet of glass, in which greenhouses he grows Lettuces, Radishes, Onions, Cucumbers, Tomatoes, Parsley, and Mushrooms, the latter sometimes selling at as high as 40 cents (1s. 8d.) per lb. It is estimated that the market gardeners around Denver, in addition to their large trade in Colorado, will this year receive 1,000,000 dols. (£200,000) from other States. A number of them are Englishmen, like—THOMAS TONGE.

AN AMERICAN BEST TWENTY-FIVE VARIETIES.

A LIST of this character is ever changing, owing to valuable additions each year made by the different disseminators, and importations of novelties from England and the Continent. Many varieties of which some growers produce beautiful blooms, are almost total failures with others, but in the following list we have endeavoured to include only those that are easily grown by nearly all.

Twenty-five large blooms:—Mrs. Jerome Jones, W. H. Lincoln, Vivand Morel, Mutual Friend, Major Bonnaffon, Mayflower, Eugène Dailledouze, Mrs. Henry Robinson, Golden Wedding, Madame Felix Perrin, Minerva, Mlle. M. A. de Galbert, Modesto, Silver Cloud, Charles Davis, Golden Gate, Mrs. S. T. Murdock, Miss Minnie Wanemaker, Helen Bloodgood, Marguerite Jeffords, Philadelphia, Mrs. Geo. West, Maud Dean, Nyanza, and John Shrimpton. The last named, though not as large as the rest, is the best and easiest grown red. This list does not include any of the novelties of 1897, which will no doubt push one or more out of this list.

The best twelve for pot plants are W. H. Lincoln, Ivory, Agnes L. Dalskov, L. Canning, Minerva, C. B. Whitnall, Golden Hair, Henry Hurrell, Louis Boehmer, Geo. W. Childs, Mutual Friend, and Constellation.—E. A. WOOD (in "American Florist").

THE BEST VARIETIES.

IN my notes *re* "Best Varieties" (page 38) I stated that Mr. Lees omitted *Etoile de Lyon* from his list. This I find is an error on my part, for which I apologise to Mr. Lees. The varieties *Georgina Pitcher*, *Mlle. Lawrence Zédé*, and *Madame G. Bruant*, although omitted from the list of fifty, are mentioned by this grower in a list of twenty new varieties, and when I made a comparison between the list of the best fifty and sixty varieties as given by Messrs. Lees and Wells I overlooked the separate class of the last named. "Mrs. J. J. Glennen" should read "Glessner," and "Dr. Ziebert" "Dr. Liebert" in my list of last week.—W. J. G.

[In an early issue we shall publish a list of the best "Chrysanthemums up to date" as determined by upwards of thirty leading growers and judges, who have opportunities for examining new as well as old varieties at the London or chief provincial shows.]

I SEE that Mr. Wells' selection of the best sixty Japs (page 624) comes in for some criticism at the hands of Mr. Godfrey in your last week's issue. It is almost impossible to select sixty varieties, each of which would be above criticism. Reference is also made to the best twenty-four Japs. I would select the following:—G. J. Warren, *Madame Carnot*, *Australian Gold*, *Phœbus*, *Edith Tabor*, *Ella Curtis*, *Georgina Pitcher*, *Simplicity*, *Mrs. H. Weeks*, *Mrs. J. Lewis*, *Lady Hanham*, *Chenon de Leché*, *C. Davis*, *V. Morel*, *E. Molyneux*, *Thomas Wilkins*, *G. W. Palmer*, *Australie*, *Royal Standard*, *Etoile de Lyon*, *Eva Knowles*, *J. Bidencope*, *Duke of York*, and *Lady Ridgway*. If the above were shown in good form I think neither *Modesto*, *Oceana*, *Western King*, nor *Lady Byron* would be good enough for comparison with them. *International* I would not grow.

Mr. Wells' selection of fifty incurved is also open to criticism. He does not think either *Miss D. Foster* or *Miss V. Foster* worth a place. Both these varieties were sent out last year, and were shown on all the leading stands throughout the kingdom—viz., first twenty-four Southampton, first twenty-four Portsmouth, first twenty-four Birmingham, first twenty-four Aquarium, first thirty-six Aquarium, first twelve incurved novelties (Mr. Wells' own stand), and first at Winchester, not to mention others.

Mr. Molyneux, writing in the *Journal* (see page 420), says, "Both these varieties possess all the characteristics needful to make sterling exhibition varieties," and yet Mr. Wells ignores them both, but includes five of the Teck family in his selection. Surely some explanation should be forthcoming.—F. G. FOSTER.

PRESENTATION TO MR. J. W. WILKINSON.

THE popular Secretary of the Royal Aquarium, Mr. James Watson Wilkinson, who is about to be married to Miss Frances W. Blacklaws, was (last week) at the Westminster Palace Hotel presented by Mr. Sheriff Dewar, on behalf of the subscribers, with a purse of £100 and an illuminated address. Mr. R. Dean, who presided, said that Mr. Wilkinson had been associated with the Royal Aquarium from its foundation, and he, like the other subscribers, had good reason to believe that much of the success which had been achieved of recent years was due to the esteemed Secretary's energetic discharge of his duties. Mr. C. E. Field then read the address, which was in the following terms:—"This tribute of esteem, together with a purse of sovereigns, is presented to Mr. J. W. Wilkinson by a few friends on the occasion of his marriage, with the warmest good wishes for his future happiness and continued prosperity, and also in recognition of his many kind qualities and courtesy always evinced in both business and social life." Votes of thanks to the officials who had

organised the testimonial brought the proceedings to a fitting close. The Committee consisted of Messrs. C. J. Noble, H. Cheesman, C. E. Field, L. del Bono, J. Mortimer Dudman, James Willing, jun., A. T. Cates, R. Dean, R. Ballantine, H. J. Jones, H. W. Wieland, G. C. Fricker, and W. A. Holmes.—J. C. (from the "Daily Chronicle").

THE N.C.S. AND THE R.A.

AN incident occurred last week that has no doubt been observed by the members of the N.C.S. generally, which helps materially, were it needed, to throw additional light on the close relations which exist between the officials of the Royal Aquarium and certain leaders of the N.C.S. Surely, henceforth, after this display of *arcades ambo*, the motto of these joint personages must be *par nobile fratrum*. I observed that over a festive board at which Mr. Wilkinson, the Secretary of the R.A., was the guest, Mr. R. Dean, Secretary to the N.C.S., presided, and he was supported, so it is reported in the papers, by Mr. R. Ballantine, Mr. H. J. Jones, and Mr. W. A. Holmes. I notice that the names of the Chairmen of the Executive Committee and the Floral Committee were absent. I trust the officials present at that festive board were there as friends and supporters of the R.A., and not as representatives of the N.C.S., though the Chrysanthemum community will naturally think they were the delegates of the Society.

In such a phase of the subject we see here illustrated how the old Hackney Society clings to the so-called "National." The term is a distressing misnomer. Were the Society termed the Royal Aquarium Chrysanthemum Appendage then would it be fitly named. Readers will not fail to notice amongst the persons reported as being present at this gathering one whose name as a prospective Secretary has been referred to. Without a doubt there is an intention to get this youth into the office of Secretary later, if the members of the N.C.S. are so weak as to allow themselves to be overborne by a name. No greater mistake could be made were this fatal policy carried out.

What is needed in the N.C.S. officials is freedom from old associations, capacity to manage on independent lines prescribed by the Committee, and a firm resolution to make the National Society worthy of its appellation. To maintain it as an appendage of the R.A., such as it now is, is to degrade it beyond all the degradations our glorious profession of horticulture has ever experienced. What is to be done? There are two courses. Every member of the N.C.S. who detests existing arrangements can attend at the annual general meeting and vote against the re-election of every R.A. supporter and apologist; or every such member can withdraw from the Society and proceed to form a new one truly national in its aims and objects. To aid this end the National Amateur Gardeners' Association should present a formidable force. There must be either mending or ending, for, as Mr. Moorman suggests, the present position is intolerable.—A MEMBER.

THE RESCUE OF THE N.C.S.

PRIOR to the disclosures of the Secretary, as elicited and recorded by Mr. Moorman, few persons could have imagined that what was universally supposed to be the strongest of our special floral societies is in its present deplorable condition.

Hundreds of persons at home and abroad who contribute to the funds, under the impression that the Society is strong and independent, must have been startled by the Secretary's statement, that it could not exist without the Aquarium. What a confession of impotence on the part of the N.C.S. Committee, of which the paid Honorary Secretary is of course the exponent!

It is due to this official to say that he has the courage of his convictions, for so certain is he of the inability of the Society to stand alone, that he has threatened to resign if a separation is effected between this "National" Society and the smoking, dancing, drinking, and home of amusement building to which it is enchained.

After the enormous sums of money which have been contributed by members over a period of years, and the scores of thousands of shillings which must have been paid by visitors to the several shows, if the disclosures and admissions of the Secretary, emphasised by his notification of resignation if the Society ventures to stand alone—if all this does not amount to an impeachment of the Chairman and Committee for incapacity in management, it would be interesting to know what it really does mean.

It must never be forgotten that the Secretary is not responsible for the existing state of things. The Committee is responsible. It cannot be supposed for a moment that the members of this Committee are other than earnest honourable men, who give their time gratuitously in furthering the objects which the Society was established to promote. But the best of men, or men with the best of intentions, are not always the strongest men. We may applaud them for their good intentions, but if they allow themselves to be misled, or their functions usurped and policy dictated by some more pushful personality, they are all the same responsible for the results.

Are the members of the Committee of the so-called "National" Chrysanthemum Society, and its Chairman, who occupies an important and responsible position in the horticultural world, satisfied with the Society's present condition and subservient connection? If so, let them say so, and clear the air. If they are not masters of the Society, as "On-looker" suggested on page 39, but mastered, there are absolutely only two legitimate alternatives—resignation, or the removal of any obstacle of an obstructive character.

The policy of the past has confessedly been a policy of failure. The Society, as its leading official has told us, is not independent—it cannot stand without the "crutch." Clearly, if it is to prosper in the future, and

be worthy of its name in the estimation of the world, there must either be a change of policy or a change of men. Nor is there much time to wait, for all who have eyes to see must perforce observe that the glory of the Society is departing. On the Committee rests the responsibility. —A PROVINCIAL SECRETARY.

[Communications on this N.C.S. subject are so numerous that we cannot possibly insert the whole of them. We have chosen those which appeared to present the case in different aspects; but not one letter has been excluded which was in the slightest degree favourable to the policy of the N.C.S. Committee, and of the alliance of the Society with the Royal Aquarium. Among the communications standing over, at least one writer so admirably, judiciously and dispassionately deals with the whole question, that his letter (and perhaps another or two if they proceed on new lines) will be published next week; and then we think our readers will agree that the question at issue has been placed with tolerable fulness and clearness before the Chrysanthemum world.]

AN INTERNATIONAL CHRYSANTHEMUM AUDIT IN FRANCE.

SOME of my friends of the N.C.S. will remember being asked to take part in an audit of the best fifty Chrysanthemums, which was organised by the Editor of the "Moniteur d'Horticulture" (France). The result has recently been published, and it appears that the audit is a most cosmopolitan one, for voters living in France, England, America, Belgium, Switzerland, Italy, Portugal, Austria, Greece, Tunis, Germany, Spain, Turkey, Roumania, and Monaco have sent in returns. One thousand and fifty-seven persons have taken part in the audit, and it is a remarkable testimony to the value of Madame Carnot that 1011 votes should have been recorded in its favour. The following are the names, with the number of votes recorded for the best fifty varieties:—

VARIETIES.		VOTES.	VOTES.	
Mme. Carnot	1011	Florence Davis ...	603
Le Colosse Grenoblois	997	Mme. Marius Ricoud ...	593
Mrs. C. Harman Payne...	994	Niveus ...	584
Mme. Ed. Roger	976	Wm. Falconer ...	578
Vivian Morel	971	E. Forgeot ...	561
Calvat's Australian Gold	895	Chas. Davis ...	558
Enfant des Deux Mondes	887	Philadelphia ...	557
W. H. Lincoln	876	Deuil de Jules Ferry ...	549
Hairy Wonder	809	Lilian B. Bird ...	539
Wm. Tricker	808	Duchess of York ...	532
Mme. Calvat	767	Louise ...	524
Etoile de Lyon	762	Capt. Lucien Chauré ...	503
Souvenir de Petite Amie	721	Le Mouchetotte ...	487
Col. W. B. Smith	706	Yellow Dragon ...	484
Mlle. Lucie Faure	701	Julian Hillpert ...	481
Reine d'Angleterre	689	Mme. Ph. Rivoire ...	463
Waban	682	Ma Perfection ...	442
M. Chenon de Leché	661	Henry Jacotot Fils ...	431
Louis Boehmer	660	Mme. Lucien Chauré ...	428
Amiral Avellan	643	Belle des Gordes ...	326
Edwin Molyneux	639	Eda Prass ...	421
L'Isère	631	Robert Owen ...	419
Mrs. Hy. Robinson	623	Mme. Chappuis Parent ...	427
N.C.S. Jubilee	614	The Queen ...	411
Phœbus	605	M. Panckoucke ...	408

—C. HARMAN PAYNE.

HONOURS FOR CHRYSANTHEMUM GROWERS.

ON the occasion of the Brussels Chrysanthemum Show M. Anatole Cordonnier, who was a very successful exhibitor in a class for 150 cut blooms, was appointed Chevalier of the Legion of Honour. We are pleased also to record that M. H. Fatzer, a well-known cultivator, and one of the first to grow big blooms in France, has just been appointed Chevalier of the Mérite Agricole. M. de Reydellet, the veteran seedling raiser, has also been the recipient of a like distinction.

CHRYSANTHEMUM SHOW AND CONGRESS AT LILLE.

WE are asked to give publicity to the fact that the Northern French Chrysanthemum Society will hold an International Show and Congress at Lille on the 10th of November next. Amateurs and nurserymen of all nationalities are invited to take part in the proceedings, which will be held in the Palais Rameau, a splendid building, well adapted for the purpose. The schedule will be published before long. Lille being only six hours distant from London, it is hoped by the Executive of the Society that English growers and amateurs will muster in strong force.—P.

MADAME CARNOT.

IN answer to the inquiry of "Lover of Flowers" respecting Chrysanthemum Madame Carnot, I adopted the following method last season with most satisfactory results, and better flowers could not have been wished for. The cuttings were rooted in December, and the plants steadily grown till the natural break occurred. From this break three shoots were selected, which were allowed to grow about 5 inches long, when the points were taken out of each of them. Other growths soon followed, and the next buds were secured during the third week in August. Some plants were topped in April and run on to the second crown; but the plants so treated did not produce such fine blooms as did those that were subjected to the treatment first mentioned.—H. S., Dorking.

ROYAL HORTICULTURAL SOCIETY.

THE COMMITTEES FOR 1898.

FULL particulars of the exhibitions of the Society can be had from the "Arrangements for 1898," in which are also given lists of the various Committees, and these we reprint for the benefit of our readers.

SCIENTIFIC COMMITTEE.

Chairman.—Sir J. D. Hooker, K.C.S.I., C.B., F.R.S., &c., The Camp, Sunningdale.

Vice-Chairmen.—Dyer, W. T. Thiselton, C.M.G., F.R.S., Royal Gardens, Kew; Foster, Professor M., Sec. R.S., Great Shelford, Cambridge; Masters, Maxwell T., M.D., F.R.S., &c., Mount Avenue, Ealing, W.

Hon. Secretary.—Rev. Prof. G. Henslow, M.A., F.L.S., Drayton House, Ealing, W.

Allen, J., Park House, Shepton Mallet.
Baker, J. G., F.R.S., Royal Gardens, Kew.
Balfour, Prof. I. B., F.R.S., Botanic Gardens, Edinburgh.
Bonavia, Dr. E., 5, Harrington Mansions, South Kensington.
Burbidge, F. W., M.A., F.L.S., Trinity College Gardens, Dublin.
Church, Prof. A. H., M.A., F.R.S., Shelsley, Kew Gardens.
Darwin, Francis, F.R.S., Wychfield, Huntingdon Road, Cambridge.
Dod, Rev. C. Wolley, Edge Hall, Malpas, Cheshire.
Elwes, H. J., F.L.S., F.Z.S., Colesborne, Andoversford, Glos.
Engleheart, Rev. G. H., M.A., Appleshaw, Andover.
Farmer, Prof. J. B., M.A., Royal College of Science, South Kensington.
Frankland, E., F.R.S., The Yews, Reigate Hill, Reigate.
Godman, F. DuCane, F.R.S., 10, Chandos Street, Cavendish Square.
Lindsay, R., Botanic Gardens, Edinburgh.
Llewelyn, Sir J. T. D., Bart., F.L.S., Penllergaer, Swansea.
Lynch, R. Irwin, A.L.S., Botanic Gardens, Cambridge.
Maxwell, W. H., Munches, Dalbeattie, N.B.
McLachlan, R., F.R.S., Westview, Clarendon Road, Lewisham, S.E.
Michael, A. D., F.L.S., Cadogan Mansions, Sloane Square, S.W.
Morris, D., C.M.G., M.A., F.L.S., D.Sc., 14, Cumberland Road, Kew.
Müller, Hugo, Ph.D., F.R.S., 13, Park Square East, Regent's Park.
Oliver, F. W., D.Sc., F.L.S., 10, Kew Gardens Road, Kew.
Plowright, C. B., F.L.S., 7, King Street, King's Lynn.
Russell, W. J., F.R.S., Ph.D., 34, Upper Hamilton Terrace, N.W.
Scott, D. H., M.A., Ph.D., F.R.S., F.L.S., The Old Palace, Richmond, S.W.
Sutton, A. W., F.L.S., Reading.
Veitch, H. J., F.L.S., King's Road, Chelsea, S.W.
Ward, Prof. Marshall, F.R.S., The Laurels, Englefield Green, Staines.
Wilson, Geo. F., F.R.S., Heatherbank, Weybridge Heath.

FRUIT AND VEGETABLE COMMITTEE.

Chairman.—Crowley, Philip, F.L.S., Waddon House, Croydon.

Vice-Chairmen.—Balderson, H., Corner Hall, Hemel Hempstead; Bunyard, Geo., The Royal Nurseries, Maidstone; Rivers, T. Francis, Sawbridgeworth.

Secretary.—Wilks, Rev. W., Shirley Vicarage, Croydon.

Barron, A. F., Sutton Court Road, Chiswick, W.
Bates, W., Poulett Lodge Gardens, Twickenham.
Bennett, W., Rangemore Park Gardens, Burton-on-Trent.
Cheal, Joseph, Crawley, Sussex.
Crumph, W., Madresfield Court Gardens, Malvern.
Cummins, G. W., The Grange Gardens, Wallington.
Dean, A., 62, Richmond Road, Kingston, S.W.
Divers, W. H., Belvoir Castle Gardens, Grantham.
Dunn, Malcolm, The Palace Gardens, Dalkeith, N.B.
Empson, W. J., Ampthill House Gardens, Beds.
Farr, W., Spring Grove House Gardens, Isleworth.
Fife, Robert, Dobbie's Nurseries, Orpington, Kent.
Gleeson, W., Warren House Gardens, Stanmore.
Herrin, C., Dropmore Gardens, Maidenhead.
Iggulden, W., North View, Frome, Somerset.
Laing, J., jun., Forest Hill, S.E.
Lane, Fred. Q., Berkhamsted.
McIndoe, James, Hutton Hall Gardens, Guisborough.
Miles, G. T., Wycomb Abbey, High Wycomb.
Norman, G., Hatfield House Gardens, Hatfield.
Parker, R., Goodwood, Chichester.
Pearson, A. H., The Nurseries, Chilwell, Notts.
Pope, W., Highclere Gardens, Newbury.
Poupart, W., Marsh Farm, Twickenham.
Reynolds, G., The Gardens, Gunnersbury Park, Acton.
Sage, G. H., Ham House Gardens, Richmond, S.W.
Saltmarsh, T. J., The Nurseries, Chelmsford.
Smith, James, The Gardens, Mentmore, Leighton Buzzard.
Veitch, J. H., King's Road, Chelsea.
Veitch, P. C. M., The Royal Nurseries, Exeter.
Ward, H. W., Lime House, Rayleigh, Essex.
Willard, Jesse, Holly Lodge Gardens, Highgate, N.
Woodward, G., Barham Court, Teston, Maidstone.
Wright, John, 8, Rose Hill Road, Wandsworth.
Wythes, G., Syon House Gardens, Brentford.

FLORAL COMMITTEE.

Chairman.—Marshall, William, Auchinraith, Bexley.

Vice-Chairmen.—Fraser, John, The Nurseries, South Woodford; Paul, George, The Old Nurseries, Cheshunt.

Secretary.—T. Humphreys, R.H.S. Gardens, Chiswick, W.

Bain, W., The Gardens, Burford Lodge, Dorking.
 Barnes, N. F., Eaton Gardens, Chester.
 Barr, W., 12, King Street, Covent Garden, W.C.
 Beckett, E., Aldenham House Gardens, Elstree.
 Blick, Chas., The Warren, Hayes Common, Beckenham.
 Cannell, H., Swanley, Kent.
 Cant, Cecil G., Colchester.
 Cook, E. T., 9, Fairlawn Grove, Chiswick.
 Crane, D. B., Archway Road, Highgate, N.
 Cutbush, H. J., The Nurseries, Highgate, N.
 Dean, R., Ranelagh Road, Ealing, W.
 Drnery, C. T., F.L.S., 25, Windsor Road, Forest Gate.
 Fitt, J. H., The Frythe Gardens, Welwyn.
 Fraser, John, Willow Cottages, Kew.
 Gordon, G., Endesleigh, Priory Park, Kew.
 Herbst, H., Kew Road, Richmond.
 Howe, W., Park Hill Gardens, Streatham Common.
 Jeffries, C., Boston House Gardens, Brentford.
 Jennings, J., Ascott Gardens, Leighton Buzzard.
 Jones, H. J., Ryecroft, Hither Green, Lewisham.
 Laing, J., Forest Hill, S.E.
 Lowe, R. B., Ashridge Gardens, Berkhamsted.
 McLeod, J., Dover House Gardens, Rochester.
 May, H. B., Dyson's Lane, Upper Edmonton.
 Mawley, E., Rosebank, Berkhamsted.
 Molyneux, E., Swanmore Park Gardens, Bishop's Waltham.
 Nicholson, G., Royal Gardens, Kew.
 Pawle, J. D., 12, Stanley Gardens, Willesden Green, N.W.
 Pearson, C. E., Chilwell, Nottingham.
 Peed, T., Roupell Park, West Norwood.
 Salter, C. J., Woodhatch Gardens, Reigate.
 Sanders, T. W., 124, Embleton Road, Lewisham.
 Selfe-Leonard, H., Hitherbury, Guildford.
 Stevens, Geo., St. John's Nursery, Putney.
 Thomas, Owen, Royal Gardens, Windsor.
 Turner, H., Royal Nurseries, Slough.
 Walker, J., Ham Common, Surrey.

ORCHID COMMITTEE.

Chairman.—Veitch, H. J., F.L.S., Royal Exotic Nursery, Chelsea, S.W.

Vice-Chairmen.—Courtauld, Sydney, Bocking Place, Braintree; Lawrence, Sir Trevor, Bart., 57, Prince's Gate, S.W.; Schröder, Baron, The Dell, Staines.

Hon. Sec.—O'Brien, James, West Street, Harrow-on-the-Hill.

Ashworth, E., Harefield Hall, Wilmslow, Cheshire.
 Ballantine, H., The Dell Gardens, Staines.
 Bond, T. W., Elstead House Gardens, Godalming.
 Brooman-White, R., Ardarroch, Garelochhead, N.B.
 Broome, Joseph, Sunny Hill, Llandudno.
 Burberry, H. A., Highbury Gardens, Birmingham.
 Chapman, H., Cambridge Lodge, Flodden Road, Camberwell.
 Cobb, W., Broadwater Down, Tunbridge Wells.
 Cookson, Norman C., Oakwood, Wylam-on-Tyne.
 Crawshay, De Barri, Rosefield, Sevenoaks.
 Douglas, James, Edenside, Great Bookham.
 Fowler, J. Gurney, Glebeland, Woodford.
 Gabriel, J. T., 32, Palace Road, Streatham Hill.
 Handley, Rev. E., 19, Royal Crescent, Bath.
 Hardy, Fred, Tyntesfield, Ashton-on-Mersey.
 Hill, E., Tring Park Gardens, Tring.
 Jacomb, F. C., Cheam Park, Surrey.
 Jaques, J., Waddesdon Manor Gardens, Aylesbury.
 Latham, W. B., Botanic Gardens, Edgbaston, Birmingham.
 Law-Schofield, G. W., New Hall Hey, Rawtenstall, Manchester.
 Little, H., Baronshalt, The Barons, E. Twickenham.
 Mason, Major, The Firs, Warwick.
 Pilcher, Charles, 84, Ringford Road, Wandsworth, S.W.
 Pollett, H. M., Fernside, Bickley, Kent.
 Protheroe, W. H., 67, Cheapside, E.C.
 Sander, F., St. Albans.
 Smee, A. H., Wallington, Surrey.
 Thompson, W., Walton Grange, Stone, Staffs.
 Thorne, F. J., The Gardens, Sunningdale Park.
 Warburton, A., Vine House, Haslingden.
 Watson, W., Royal Gardens, Kew.
 White, W. H., Burford Lodge Gardens, Dorking.
 Williams, H., Victoria Nurseries, Holloway, N.
 Winn, C., The Uplands, Selly Hill, near Birmingham.
 Young, W. H., Clare Lawn Gardens, East Sheen, S.W.

NARCISSUS COMMITTEE.

Chairman.—Bennett-Poë, John T., 29, Ashley Place, S.W.

Vice-Chairmen.—Baker, J. G., F.R.S., Royal Herbarium, Kew; Dod, Rev. C. Wolley, Edge Hall, Malpas, Cheshire; Engleheart, Rev. George H., Appleshaw, Andover.

Hon. Secretary.—Scrase-Dickins, C. R., Coolhurst Park, Horsham.

Barr, R., 12, King Street, Covent Garden, W.C.
 Boscawen, Hon. J., Tregyc, Perranwell.
 Bourne, Rev. S. E., Dunston Vicarage, Lincoln.
 Burbidge, F. W., M.A., Trinity College Gardens, Dublin.
 Cammell, G., Brookfield, Hathersage, near Sheffield.
 Cammell, M., Loxwood House, Billingshurst, Sussex.
 Cowan, C. W., Valleyfield, Penicuik, Midlothian.
 Foster, Prof. M., Sec. R.S., Shelford, Cambridge.
 De Graaff, S. A., Leyden, Holland.
 Goldring, W., 34, Gloucester Road, Kew.
 Kingsmill, A., Esq., The Holt, Harrow Weald, Stanmore.
 Krelage, J. H., Haarlem, Holland.
 Leichlin, Max, Baden-Baden.
 MacMichael, Rev. C., Walpole Rectory, Wisbech.
 Marsh, Rev. T. H., Cawston Rectory, Norfolk.
 Milne Readhead, R., Holden Clough, Bolton-by-Bowland, Clitheroe.
 Moore, F. W., Royal Botanic Gardens, Glasnevin, Dublin.
 Perry, Amos I., Hardy Plant Farm, Winchmore Hill, N.
 Smith, J. A. Dorien, Tresco Abbey, Scilly.
 Vilmorin, Henry L. De, Quai de la Mégisserie, Paris.
 Walker, James, Ham Common, Surrey.
 Ware, Walter T., Inglescombe Nurseries, near Bath.
 Wilks, Rev. W., Shirley Vicarage, Croydon.
 Willmott, Miss, Warley Place, Great Warley, Essex.

LIVERPOOL NOTES.

PUBLIC PARKS AND GARDENS.

At a meeting of the Liverpool City Council, held last week, Alderman Ball, Chairman of the Parks and Gardens Committee, stated that the estimates were the same as the previous year, but compared with those for six or seven years ago, they would notice that the expenditure to-day was much larger. No doubt the expenditure had increased, but the improved appearance of the parks, the public squares, the gardens and the churchyards, was most marked in comparison with the state of things prevailing six or seven years ago. In regard to the public parks, they had good management. Sefton Park was, doubtless, a feature of beauty, but the Committee had improved it materially, and he hoped the Council would provide them with still further means of doing so.

He was glad to say that the tubs containing shrubs, which had been placed in many streets, were a source of great pleasure to the inhabitants, while the introduction of window boxes in the poorer parts of the city had proved in every way successful. They brightened the homes of the poor. In this matter it was not the men they wanted to get hold, but their wives, who were thus led to take a keener interest in their dwellings.

During the past six years additional recreation grounds had been placed under their control, involving an increased expenditure of £3240 per year. They proposed to introduce into Sefton Park a deer park, which would be a source of great attraction to the young children. In Newsham and Stanley Parks great improvements had been made. In the former a bowling green and hut is to be formed, so as to attract the working men during the summer evenings; also a handsome fountain. In the latter a new bridge over one of the lakes, and the provision of a lake for the sailing of model yachts, a pleasure for which there was a great demand. Two aviaries are also to be formed.

Sir Thomas Hughes criticised the policy of the Committee as being extravagant, whilst Sir Arthur Forwood asked that the estimate of £25,000 be reduced by £3000. Ultimately he altered his amendment so as to reduce by £2250, this being carried by a large majority. In all fairness to the Committee it must be admitted that Liverpool has been greatly improved during the past few years in matters horticultural, and this is recognised by all visitors to the second city in the kingdom.

LIVERPOOL HORTICULTURAL ASSOCIATION.

On Saturday evening last the members and friends of the above Association to the number of over 130 met together at the Adelphi Hotel under the presidency of W. Fletcher Rogers, Esq., the Hon. Treasurer, the vice-chair being occupied by Mr. Thomas Foster, supported by Mr. J. Kellitt, C.C. In addition, there were present Messrs. Andrew Ker, H. Middlehurst, Charles Young, J. Webster (representing Messrs. T. Davies & Co.), Rowlands, H. Ranger (R. P. Ker & Sons), and other members of the trade, with Messrs. W. Dickson (Secretary) and G. Blackmore (sub-Treasurer). With the exception of the loyal toasts all others had been dispensed with. An excellent vocal entertainment was given. Mr. Kellitt, in a very happy speech, proposed a vote of thanks to Mr. Rogers, in which he spoke of the benefit derived by gardeners in their delightful study, and hoped that the Chairman would long lead such a willing body of workers. The Chairman, in reply, said that notwithstanding the many societies in their midst, he always hoped to see the Liverpool Horticultural Association at the head, and would ever be ready with his services. Votes of thanks to the artistes closed the proceedings.—R. P. R.

EELWORM DESTRUCTION.

BASIC SLAG AND KAINIT FOR CUCUMBERS AND TOMATOES.

YOUR correspondent "W. B.", on page 43, asks for less "bantering and boasting" and a little more "precise and clear information." Quite so, but why does he not set us a good example? I cannot find in my Journal that Mr. Abbey leads us to think that 12 ozs. of kainit and 2 lbs. of basic slag per square yard will "probably poison borders." "W. B." ought to read more carefully, and frame more precise and definite questions, if he wants clear information.

In answer to his inquiry, "Is it safe to plant Tomatoes and Cucumbers in borders as prepared?" we might ask, How have they been prepared? Have 12 ozs. of kainit and 2 lbs. of basic slag been applied to them? if so, who advised this amount for Cucumber borders?

If "W. B." has used the quantity of kainit and basic slag that I used in my Tomato borders, he may with safety plant his borders without any fear of injury from the compounds used. Last spring a dressing of 12 ozs. of kainit and 2 lbs. of basic slag per square yard was forked into the soil in a certain section of the house, and 200 Tomato plants were planted in the borders as soon as the digging was finished. These plants grew well and fruited excellently, the artificials having only a beneficial effect upon them. Still a few of the leaves drooped and died owing to an attack of sleepy disease fungus.

To be precise and clear I may, perhaps, be allowed to give more definite instruction. We spread 2 inches of decayed manure over the soil for Tomato borders, and then spread the basic slag and kainit on the top of this; the soil is then forked over carefully to a depth of 1 foot, mixing well together. It is necessary to do the work thoroughly, and to go to the required depth.

If we wish to mix the kainit and basic slag with the soil for our Cucumbers we must first find out about how much to use. Twelve ounces of kainit and 2 lbs. of basic slag per square yard, if forked into the top foot of soil, would be equal to mixing the artificial fertilisers with 900 lbs. of soil. This is not a very great deal after all, and I have mixed more of stronger artificials than the above in potting soil for Chrysanthemums, Pelargoniums, Cinerarias, and other plants. If "W. B." will mix the above quantity of kainit and basic slag with 900 lbs. of Cucumber soil he will find nothing but benefit follow. He must remember, however, that the blending must be complete, and that rough digging does not suffice, by which the dressings applied fall in small "heaps" between large cubes or "spits" of soil.—W. DYKE.

[An important communication by Mr. Iggulden on combating eelworms and supporting plants with soluble phenyle must perforce stand over till next week.]

A CURIOUS POTATO.

I SEND you a Potato which, I think, is a bit of a novelty. You will observe the young Potatoes are growing out of the old one.—W. BROWN.

[The prolific Potato sent by our correspondent is not such a novelty as he supposes, as it has been many times observed. It is none the less interesting, and as it is scarcely likely all our readers have seen it we furnish an illustration (fig. 11) of a precisely similar occurrence that came under our notice about seven years ago. As may be seen, the "new" Potatoes were not formed by or from the external buds or eyes, but formed in a cluster in the centre of the Potato, increased in size there, and forced their way through the dried cuticle. We assume they are the produce of latent buds on the growing axis that proceeds through the tubers from base to apex, and terminates in the buds by which the growth is continued the succeeding year; but these buds having become effete, the latent buds become active for perpetuating the kind. A portion of the old Potato was removed for showing the position of the young tubers.]

A DAY AT ALTRINCHAM.

WHEN recently visiting Messrs. Clibran's establishment at Altrincham, I was shown over their nurseries, which, at the present time, cover more than 200 acres. Glass houses alone occupy five acres, a casual look at which led one to think that everything is cultivated to the best advantage. Throughout the season there is always something of interest in the way of special exhibits, noteworthy at the time being two houses of admirably grown Cyclamens, the strain being free with flowers of great substance and variety. Chrysanthemums were just past their best, but the prizes awarded at the leading shows testify to the ability displayed by the firm to keep all up to date. Other plants having separate houses devoted to their wants were Begonias, Celosias, Carnations, Bouvardias, and Zonal Pelargoniums, whilst the stove and greenhouse departments take up a large number of houses, plants from the tiniest seedling upwards being in evidence everywhere.

Adjoining the glass houses many acres are devoted to hardy herbaceous plants and florist flowers, embracing old and new favourites, over an acre alone being occupied with the latest varieties of Pæonies, which make a gorgeous display when in bloom. Climbing plants in and out of pots are grown extensively, also many beautiful and uncommon plants suitable for wall and pillar decoration. Ascending the high ground near the nurseries one is struck by the very large number of specimen Hollies, averaging in height from 3 to 15 feet, and all of perfect symmetry. The work of

re-arranging is being carried on at intervals, and will, when completed, be a great boon to visitors; consequently the plants are always in a fit state for removal. Deciduous and ornamental trees are grown as nurses in single rows, each tree being a specimen ready for street, park, or avenue planting.

Thousands of Conifers, in splendid condition as regards colour and arrangement, are also grown. The plants are excellent in every respect. I was much struck by the care exercised in the rearing of the young trees and shrubs in open cases, to protect them from the cold winds and dry spring weather, which cause such destruction to plant life. The cases are really open frames, a slight covering of bracken being placed over the seedlings and cuttings in very severe weather, so as to prevent the frost from lifting them out of the ground.

In other sections I was astonished to see such enormous quantities of Laurels, Aucubas, named hybrids and other Rhododendrons from 12 inches to 4 and 5 feet in height, well shaped, and fit to suit the most exacting. Oval leaved Privet is grown most extensively from small hedge

FIG. 11.—A PROLIFEROUS POTATO.

plant size to large bushy specimens, for immediate effect. The Hale Farm Nurseries cover fifty acres. Forest trees, Larch, and an almost endless variety of Firs might be seen by the million, as well as the general kinds of trees for plantations and coverts. Hedge plants are a great item, one quantity of 250,000 quicks being very noticeable. In the fruit tree section there are over thirty acres planted, and trained trees of every form are highly creditable. Roses are represented by the 100,000, being grown in every position here as well as at the firm's large nursery at Llandudno, so as to get thoroughly tested, their appearance being most desirable.

Many plants have to be left without mention. The general features of the nurseries, situated as they are at various points around Altrincham, Bowdon, and Hale, afford to the visitor a pleasant treat. To those who have not had the pleasure, I advise a visit when in the district. An agreeable surprise will await them, and as foremen are to be found in each department, every facility is afforded to the visitor to look and learn. Landscape gardening seems to be a special feature, judging from the important contracts recently completed and others just taken in hand, from plans supplied by the firm.

Throughout the various nurseries there is much taste displayed in arranging the different kinds of trees in quantity so as to catch the eye, and although being well conversant with the majority of plants seen, I should be wanting in courtesy were I not to heartily thank Mr. Brown, the general manager of the nurseries, for his kind and agreeable company.—A VISITOR.

PRACTICAL ENCOURAGEMENT IN GARDENING.—We learn from a contemporary that at Llandulas, Wales, some time ago, Mr. A. L. Jones, a Liverpool merchant, distributed amongst the cottagers of the district several thousand young flowers and fruit trees, with a view to encouraging the growth of these. The matter was spiritedly taken up locally, and considerable attention is being given to flower growing, especially in the district.

FRUIT NOTES.

ADAMS' PEARMAIN APPLE.

THIS Apple should certainly find a place in every garden where dessert fruit is required. It is one of the most attractive of British Apples, and though the flesh and flavour are not equal to Cox's Orange or Ribston Pippin, it is useful, inasmuch as it will come in after these and many other kinds are over, and from January to March is its best season for eating. We have two trees, low standards, in the full sunshine, that annually furnish a crop, heavier some years than others, still when it attains a fair sized tree it is a constant bearer. The appearance of the fruit is good, which is an essential for the table. It should not be planted in the shade of other trees, otherwise it will be deficient in colour. Another essential point is that the fruiterers will always purchase good or fair samples of this Apple because they are attractive for the windows, and find a good retail sale.

NEC PLUS MEURIS PEAR.

This is another useful fruit for dessert purposes from January to March. Pears at this season are not always very plentiful. It is a second size fruit of a brownish colour, but the flavour, particularly after a fine autumn, is very fair. We have never found it crack as some late Pears do. The fruit buds set freely, and the fruit is generally picked about the end of October or first week in November. We have it as a low standard, and planted in the full sunshine. It annually produces a fair quantity of Pears, and some years is heavily laden. No doubt if grown on a wall the fruit would be better flavoured, most Pears are, and would be a useful addition for those who are short of Pears after the Christmas season is over.—A. HARDING, *Orton*.

POTATO DISEASE IN THE COUNTY COURT.

ONE of the most wonderfully arrived-at decisions that has come under my notice was achieved at the Bradford County Court recently. If it is to stand as a precedent it will be one of the most important that has ever been perpetrated in connection with the Potato trade. A Potato dealer sought to recover £11 7s. 6d. for Potatoes supplied to another, who refused to pay on the ground that they were diseased. The conditions of sale were the Potatoes were to be sold "on rail." The Judge found for the plaintiff on the ground that he was of opinion that "the substantial cause of the disease came after delivery at the station." The Judge is reported to have based his verdict on expert evidence; but surely he must have been peculiarly advised, or he took a different view of the advice than was intended, for the statements in the summary of the case, as reported in the "Mark Lane Express," are, to put it mildly, eccentric. There can be no doubt that the disease was ordinary Potato disease, "Phytophthora infestans." His Honour, in explanation, said, "the infection might be carried by a man who had been handling a bad Potato subsequently picking up a good one to look at it, and then putting it back in a pie, and the whole pie had been known to be destroyed in this way."

As to carrying infection, I do not object to that; but as to a whole pie being contaminated from one tuber, I flatly deny it, and am quite sure that this statement cannot be substantiated. There is no proof that the disease can be carried from tuber to tuber when dug; what is more, the evidence is against conidia being formed on tubers, and therefore germs cannot be given off to start it from tuber to tuber. It is equally certain that the mycelia, or root threads, in one tuber do not spread from tuber to tuber. If the spores of the disease happened to be resting on the other tubers, sweating would be sufficient to set up disease, as the warmth and the moisture settling on the tubers would be favourable to germination and subsequent growth. This is very common: and what is more, there is little doubt that it was from spores which settled on the tubers while being dug that the Potatoes in question suffered, particularly as the Judge himself stated a portion of the crop not sent away contained disease.

Another erroneous conclusion the Judge drew was that if the spores which were on the tubers at the time had begun to germinate, so as to effect them, it would have been visible. This is by no means the matter of course he said it was. The spores are so small that several thousands are required to reach an inch if laid alongside one another. Moreover, the disease is not noticeable to the naked eye until it has developed root threads, and they in their turn have brought about putrefaction, the rapidity of which is largely due to the temperature.

That fewer Potatoes among those which were left were diseased does not prove anything. If they were dug later in all probability the spores had fallen from the leaves, whereas at the time of digging they may have fallen directly on to the tubers. This is the common cause of after-disease, and one which anyone who has the slightest pretensions to a knowledge of the disease cannot fail to have become cognisant of. It might have been that the other Potatoes were dug on a drier day, or the skins may have become more hardened, and therefore more difficult for the germ to penetrate. His Honour, however, held it was more likely that the spores were carried on to the Potatoes after they were placed in the truck, having been wafted on the air. One knows that when Potato disease is rampant the air is largely charged with spores; but the farther from a diseased field the scarcer do they become. There are other points in connection with the judgment based on deductions from "scientific" evidence which are as strange as those dealt with here; it is not necessary, however, to go further to show how dangerous it is to

handle subjects on very limited knowledge. If the verdict is to be upheld in the future, it will be necessary for those dealing in Potatoes during the digging season to have them microscopically examined at the moment of delivery and acceptance; or some other Judge without a profound knowledge of fungal disease may make a verdict which will go to prove the old adage that a little knowledge is a very dangerous thing—but the Judge will not be the sufferer.—W. J. MALDEN (in "North Wales Chronicle.")

EQUAL PRIZES.

I QUITE agree with Mr. Beckett (page 17) when he says it is possible that two exhibits of a similar nature may be so absolutely equal as to necessitate an equal prize being awarded. It has been my lot on several occasions when assisting as judge at shows to award an equal prize.

In many instances vegetables, and especially Onions, Carrots, and Potatoes, have been of such equal merit on all points that we have felt it unfair to place the two exhibitors first and second, and the decision has generally met with the approval of the executive of the show, the exhibitors concerned, and the general public. It may often happen that the other exhibits in the same class are a great many points behind these first two, and when such is the case no second prize is awarded, but two firsts, and then a third; the money value of the first and second prize is added together and divided between the two equal firsts.

One instance occurs to my memory of a July show in one of our Fen towns, where vegetables are well grown, and are quite a feature of the exhibition. It was a class for "Six Onions, autumn sown." The variety in both cases was the Lemon Rocca. Both sixes in appearance and finish were exactly alike, and each bulb was minutely examined for any blemish, but there was none, and even when tested with a pair of scales they were found to be exactly the same weight. It really looked as if these two exhibits were from the same garden; but such was not the case, as we found out afterwards that the two exhibitors were old opponents in the art of showing well grown vegetables.—A. HARDING, *Orton*.

CALIFORNIAN EXPERIMENTS.

WE find from the report, by Mr. E. J. Wickson, of the Agricultural Experiment Station of the University of California, that 27,329 plants and roots were distributed during the past season. We also observe that attention has been widely called of late to the desirability of the Camphor tree (*Cinnamomum camphora*) for growth in California valleys and foothills either as an ornamental tree or as a possible source of profit for its timber and for the gum and oil which are derived from it by simple distilling processes. The Camphor tree was introduced to California at least twenty-five years ago, and was among the first plants distributed from the University. There is therefore at the present time ample demonstration of the hardiness, drouth-resistance, and beauty of the tree, and, so far as its growth is concerned, it is an eminently safe tree to plant for ornamental or forest purposes. Concerning profit to be derived from its planting we do not undertake to give assurance. The tree is a handsome, broad-leaved evergreen, attaining large size and noticeable by the characteristic light green of its foliage. It endures in California a temperature as low as 20° Fahr., and is probably about as hardy as the Olive. The report also contains the following notification:—

Plants for Green-Manuring.—We are still pursuing our effort to secure a leguminous plant which will prove satisfactory for green-manuring in California. As explained in earlier publications of the Station, it is necessary to have a plant which will make a heavy growth during the winter months, so that it can be ploughed in early in the spring and the ground put in shape for the thorough surface pulverisation which largely prevents evaporation of moisture during our long, dry summer. For this reason we cannot use many plants which are used for green-manuring in humid climates. Crimson Clover, Cow Peas, &c., do not make good winter growth. The square-pod Pea (*Lotus tetragonolobus*) is better, but still too scant in its winter growth. The common "Bur Clover" (*Medicago denticulata*) and its near relative "Snail Clover" (*M. turbinata*) are proving very satisfactory in some parts of the State, and the "Canadian Field Pea" is coming into quite wide use in some of the southern Citrus orchards. Experiments are also in progress with the native Lupins which may yield valuable results. We offer this year still another plant for trial, which we desire to have planted on a small scale in many localities to determine its hardiness and thrift under our winter conditions of heat and moisture—namely, Fenugreek (*Trigonella fenum-græcum*). This is an old plant of the Mediterranean region. It is of the Clover tribe; an annual which, under favourable conditions, produces a heavy weight of stem and foliage. It is used in the old countries for hay-flavouring; the seed also has aromatic quality and special uses in veterinary medicine. But it is rather for its possibilities in the green-manure line that we desire its trial, and this use is suggested by the report of the Director of the Botanical Service of Algeria and Tunis, which mentions a trial of Fenugreek sown in the autumn which produced by the 1st of the following March a weight of 25 tons per acre of green forage. The part of the field which was allowed to ripen produced about 1400 lbs. of seed per acre. We wish to determine by local trial whether the plant will endure our winter frosts, and, if so, whether its winter growth is greater than that of other legumes mentioned above. The availability of Snail Clover for green-manuring, especially in regions of abundant winter rains, has been approved by a number of experimenters during the last year.

ANTIRRHINUMS.

FEW hardy perennials are capable of being so readily raised from seed and flowered in so short a time as the Antirrhinum or Snapdragon. The dwarf varieties are eminently suitable for bedding and the taller for borders, where they will furnish spikes of bloom for cutting over a considerable period. The dwarf varieties, too, may also be employed for cutting when the plants are growing luxuriantly and flowering from every side shoot. Sutton's Tom Thumb strain is the best I have cultivated. Seed sown in March has produced plants which bloomed in July, not only profusely, but in admirable variety, distinct yellow, white, and crimson varieties being very conspicuous. There are also brilliant intermediate shades, the whole, when mixed and planted in one bed, producing a most effective display. It is possible to obtain the different colours separately in planting a bed, or any combination desired.

The present month or early in February is an excellent time for sowing the seed. A strong temperature is not essential. Prepare some light sandy compost consisting of old potting soil, a little fresh leaf soil and silver sand. Place this in a moist state in drained pans or shallow boxes, covering the drainage with damp moss or fibre. When the compost has been levelled and made firm, give a gentle watering with warm water. After draining freely sow the seed thinly. A dusting of fine sand over the surface will show where the seed falls. It is very small, and not easily distributed as thinly as desirable. Merely cover the seed from view by a layer of soil sifted through a fine sieve. Cover the pans or boxes with a pane of glass, and over that, paper to exclude light and lessen evaporation. Place them on a shelf in a warm greenhouse or other structure. No water should be needed or applied until the seed has germinated, but, better still, until the seedlings have become strong and established.

Plenty of light will soon effect this. The pans or boxes may then have a cooler position, but still abundance of light must be accorded them or they will quickly lengthen, at the same time weakening. This causes them to be liable to attack from the fungus which frequently infests the stems of various seedlings, but more especially when somewhat crowded. A sufficiency of air, light, and a healthfully moist condition of the soil are the chief requirements of the seedlings. Under these conditions, and having room to develop sturdily, it may not be requisite to prick them out to strengthen further. It will be better, however, to do so rather than crowding should be tolerated, as it is not desirable to plant out in the open before early in May.

Young plants just commencing to branch from the nodes may be planted 6 inches apart. At this stage they will be furnished with a number of fibrous roots, so there is no difficulty in establishing them permanently. Even in a still younger state, and the seedlings have experienced no crowding, they transplant well. Early sowing produces seedlings in time for pricking out in boxes or frames in order that each may assume a sturdy habit, and thus take advantage of the abundant space and rich root run to advance rapidly to a flowering state.

For general utility a bed of mixed colours will serve the most useful purpose, either for decoration or cutting. Admirable effects may be produced by planting small beds of one colour only, the dwarf or Tom Thumb being far preferable to any other, owing to its low and bushy habit of growth.

Varieties of intermediate and tall growth are suited to the mixed border, elevated and sloping banks, between and in front of shrubs, or in any position and soil where light is not denied them.

During the early stages of growth, while vacant spaces remain between the plants, the soil should be kept loose on the surface, especially when becoming dry after rain or artificial waterings. The Antirrhinum is a plant well adapted for a semi-shady but yet open position, as well as sunny aspects. The soil may be fairly rich and light, enriched with decayed manure or leaf soil.—S., *Gravesend*.

AUSTRALIAN FORESTRY.

THE increasing use of Australian timbers for wood-paving purposes has naturally directed attention to capabilities of the various colonies as permanent sources of supply, the general impression being that in this respect Western Australia takes the lead. This, however, is an erroneous assumption, for, according to Mr. Coghlan, the New South Wales Government Statistician, the Australian mother colony possesses a wealth of timber surpassed by only a few other countries. Its woods are as varied as they are valuable, ranging from the Ironbarks, unsurpassed for work requiring hardness and durability, to the kinds suitable for the most delicate specimens of the cabinetmaker's art.

Indiscriminate felling has, however, made several kinds comparatively rare, a frequent experience in newly settled countries, where the leading object of the pioneer residents is almost invariably to get rid of the timber on the lands occupied by them. The necessity of preserving the timber resources of the colony, and preventing the ruthless destruction of the best species of brush and hardwood which was being carried on, principally in the Clarence River district and in the Eucalyptus forests on the Murray, led the Government, in 1871, to establish a certain number of forest reserves throughout the colony, in which permission to cut timber, under certain conditions, should be granted upon payment of a fixed fee. Subsequently, in 1875, the office of Forest Ranger was created, and this led to the formation, in March, 1882, of a Forest Conservation Branch, which was attached to the Department of Mines.

Seven years later the colony was subdivided into a number of forest districts. These are frequently inspected by forest rangers, whose duty it is to report on the existing state of the proclaimed reserves, control the operations of licensed timber-getters, receive royalties on the various kinds of timber upon which such dues may be levied, and report upon applications to ringbark trees on Crown land, whether comprised in forest reserves or otherwise.

In view of the importance of the timber resources of the colony, the Hon. J. H. Carruthers, Minister for Lands, is preparing a bill, the main feature of which will be the establishment of permanent forestry reserves, where the timber can not only be used as it matures, but where steps can be taken to create a new supply to take the place of the trees which may be felled. This feature of the establishment of permanent reserves is, the Minister says, the chief matter to be considered, and it will apply mainly to the coastal forests, to the Red Gum forests on the Murray, and to the Ironbark forests all over the colony. With regard to the Pine forests, it is recognised that a different system will have to be adopted, because Pine is a timber of rapid growth, and, indeed, in many instances it is nothing more nor less than a noxious weed. In the meantime much has been already effected in the direction indicated.

During the last two years about 60,000 acres of Red Gum, 30,000 acres of Pine, and 2000 acres of coastal forests have been improved by thinning out and destroying the superabundant growths. This work has been carried out with the object of insuring the maturity of a larger number of trees to the acre, and, by reason of the additional light and air afforded, of their reaching that stage in about two-thirds of the time that would be taken under natural conditions. The cost of the thinning out operations averages 5s. 8d. per acre in the Red Gum areas, 4s. 6d. in the Pine areas, and 7s. in the coastal areas, and it is estimated that this outlay will return during the next twenty years two or three hundred marketable trees to the acre where the present unimproved average is but four or five. The Forest Conservation branch is charged with the direction of a State forest nursery, which is situated at Gosford, in the beautiful district of Brisbane Water, about fifty miles from Sydney, where the acclimatisation of valuable foreign timber trees, and the conservation of such of the best indigenous species as might otherwise be likely to disappear, are attended to. The area set apart for the nursery is 65 acres, of which 25 acres are cleared and cultivated.

Among the indigenous trees which are raised there may be mentioned Tallow-wood, Blackbutt, Beefwood, Silky Oak, Yellow Pine, the best varieties of Ironbark, and Red Cedar, the Red Cedar seedlings on hand at the close of 1895 numbering about 32,000. Of late, special attention has been paid to the cultivation of the White Mulberry, in expectation of a demand for this tree in consequence of the increased interest taken in the cultivation of silk in the colony. It is estimated that there are 28,000 Mulberry trees of different varieties, in various stages of growth, in the nursery, besides nearly 100,000 exotic trees of economic value. In addition to reforesting the Crown reserves with the best classes of timber, the State forest nursery distributes specimens among settlers in the sparsely timbered areas in the western district of the colony, and supplies them to municipalities, to the trustees of public reserves, and for the improvement of church and school lands and for other purposes.

Altogether, from 1890 to the end of 1896, over half a million plants were sent out of the nursery, the number for 1896 being 24,769, of which 11,120 were supplied to public bodies and private persons, and 13,649 were placed in reserves and other plantation areas. The number of merchantable plants remaining in the establishment on the 1st January, 1897, was estimated at 104,040—viz., 21,200 in pots, 17,100 seedlings in boxes, and 65,740 plants open-rooted. The consumption of Wattle bark is very great in this colony, where it is in large demand for tanning purposes. During 1895, 80,770 cwt. of Wattle bark were imported, valued at £19,634, nearly 68,000 cwt. of this supply being obtained from Tasmania. It will thus be readily seen that there is room for a large development of the trade in New South Wales. The department has taken steps to prevent the indiscriminate stripping of the bark, and the destruction of the trees, and thus stimulate the trade.—J. PLUMMER, *Sydney, N.S.W.*

THE YOUNG GARDENERS' DOMAIN.

CYCLAMENS.

FEW plants are better adapted for winter and spring decoration than varieties of *C. persicum*, and few plants produce such a profusion of flowers in return for the moderate amount of care required. The propagation of the Cyclamen is effected by seeds, which are never in better condition for sowing than when freshly gathered. An excellent time for sowing is at the end of July or beginning of August, when shallow pots or pans should be half filled with crocks, the compost consisting of light sandy soil. Scatter the seeds thinly and evenly on the surface, and then press it in and cover thinly, placing a piece of glass over the pan or pot. A temperature of 60° will be sufficient to insure germination, and when the seedlings appear they must be placed close to the glass in a light position. When large enough put singly in thumb pots, and keep like this in a similar temperature till spring, when they may be placed in 3-inch pots and grown in cool frames during the summer, admitting plenty of air after they are established.

Shading during bright sunshine and syringing on fine afternoons will be found advantageous. By June or July most of the pots will be filled with roots, and the corms will require pots 5 inches or 6 inches in diameter in which they will flower. Good drainage is very important, and deep

potting must be avoided, leaving the top of the corm, whence the flowers and leaves proceed, above the surface. Cyclamens are particularly subject to injury from green fly, red spider, thrips, and those pests should be frequently looked for. The after cultivation consists chiefly in keeping the plants in a light place close to the glass, admitting plenty of air but avoiding draughts.—J. H. C. S., *North Wales*.

FUNGUS PESTS.

THE worst pests that a gardener has to contend with in eradication are, in my opinion, the fungus pests. Red spider, thrips, and mealy bug are at times difficult to get rid of, I own, though, as a rule, they are successfully dealt with by syringing or sponging; but when we have fungoid enemies to contend with greater anxiety is entailed.

I think the most devastating invasion is that of the mildew which attacks Vines. This pest is so ravenous, as it were, in its attack, that unless speedily checked it soon destroys a whole crop of Grapes. It appears generally as very fine dust in patches, but when subjected to microscopic examination it presents a very different appearance. A rather high power is needed to define the separate parts of this fungus. It appears to be a collection of tiny plants, each complete in itself for the carrying out of its life's function. How astonishing it is that such tiny atoms should be endowed with such destructive power.

The rate at which mildew spreads is astonishing. We may see only a small patch one day, but a few days afterwards, if left to itself, it will have made such progress as to have almost covered a house of Vines. Such a case I have in my mind now. Yet when we remember that mildew is a great spore-producing plant, and that millions of spores when ripe float in the air, and are carried to different parts till a favourable spot is offered them for germination, we need not be surprised by the infestations.

All young men ought to know that mildews are parasitic plants, and that some forms live on the substances which should benefit the Vine. In such case the "host" has to supply food for the sustenance of hundreds, and sometimes thousands of plants, to its own serious detriment. Many and varied are the opinions given as to the inciting cause of mildew visitation. Some gardeners attribute it to dryness at the roots, others to stagnation of the soil, and still others to sharp chilling currents of air. It is prudent, therefore, to avoid, as far as possible, all these contingencies.

I am of opinion that the tiny spores travel great distances in the air, and are thus brought (in many instances) into contact with favourable mediums for germination. Chrysanthemums and Roses are often seriously infested with mildew, and often with disastrous consequences. In the case of Chrysanthemums the under surface of the leaves is usually attacked first, as though the enemy wished to get well established before being noticed, and where better protected against remedies applied for its destruction. I know of no better mildew destroyer on these plants than flowers of sulphur dusted over the affected parts.

A method I have seen adopted in vineries where mildew was prevalent was the placing of a small lump of fresh lime in a 24-size pot (the number of pots being determined by the size of the house), then damping it and sprinkling it with a little sulphur. Of course by damping the lime it became hot, which caused the fumes of the sulphur to rise, and I can say it proved very effectual. This method is less unsightly than painting the pipes, which in many cases is resorted to.

There are other minute fungi that play pranks with some of our most useful plants which will serve for a future article should this be inserted. I think young gardeners ought to study the minute forms of parasitic life with the aid of a microscope.—ASPIRANT.

FRUIT FORCING.

Cherry House.—No fruit tree dislikes a close stagnant atmosphere more than the Cherry, therefore ventilate early and increase the amount of air with the advancing day. Maintain a night temperature of 40°, no more, by artificial means in severe weather, 45° by day when dull and cold, 50° on mild or sunny days, ventilating at 50°, and allowing an advance to 60° or 65° from sun heat with full ventilation, closing at 50°. Syringe the house and trees in the morning and afternoon when the weather is bright, damping occasionally in dull. Trees in pots must have the necessary care in watering.

Cucumbers.—Young plants must be shifted into larger pots when they require more room, keeping them near the glass, and putting a stick to those required for trellis work. Winter fruiting plants will need surface dressings occasionally to keep them healthy, and any that exhibit signs of exhaustion will be assisted by fresh material supplied in place of as much of the surface soil as can be removed without injury to the roots, using turfy loam and a fourth of well-decayed manure, sprinkling a little fertiliser on the top. Such surface dressings incite the emission of roots, and when these are plentiful the plants can be invigorated by copious supplies of liquid manure. Keep the growths tied to the trellis, cut out exhausted parts, and tie in young shoots so as to maintain a succession of bearing wood, and consequently of fruit. Afford each growth space for development, all the foliage full exposure to light, and above all avoid overcropping.

Melons.—Plants raised early in the month are in the second leaf, and root action proceeding rapidly; therefore attend to earthing, and where the small pots are occupied with roots, either turn the plant into the fruiting quarters or transfer to the next larger size of pot, for stunted, root-bound plants never do any good. Plunge in bottom heat near the glass, a temperature of 75° to 80° being sufficient, placing a stick to each plant for its support till reaching the trellis. Plants for pits and frames can be stopped at the second rough leaf.

Soil for Melons.—Heavy loam suits Melons, the top 3 inches of a pasture cut and stacked in the autumn, chopped up moderately small, being the most suitable. An addition of manure can be made as desired, also of lime rubbish and road scrapings, when there is a deficiency of calcareous matter or of grit. If there is a suspicion of eelworm, scald with boiling water; it kills these and all other pests that feed on the Melons, either at the roots or on the tops. We have found this simple precaution very satisfactory.

Planting in Pits and Frames.—The bed must be made up about a week in advance of the stock being fit to plant out, employing thoroughly sweetened materials, put together compactly. Place a barrowful of soil in the centre of each light, flatten the top, this being about 9 inches from the glass, and the soil 10 inches deep. When warmed through place a plant in the centre of each hillock, press the soil firmly around the roots, keeping about half an inch below the seed leaves, and having the soil in the bed and pot moist, to prevent the need of water at planting. A circle of quicklime or dry soot drawn around each plant a little way from the stem will absorb superfluous moisture and be a barrier against slugs.

Peaches and Nectarines.—*Earliest Forced Trees.*—Continue the fertilising of the flowers as succeeding ones expand and the pollen becomes ripe, distributing it over the stigmas, which is more effectual than shaking the trellis. Syringing may be resorted to both morning and afternoon when the fruit is well set, but in dull weather damping will be sufficient, and in cold weather syringe sufficiently early to allow the foliage to become dry some time before nightfall. This is important, for keeping the trees constantly dripping with water encourages soft growth, is inimical to the leaves and swelling of the fruit, besides inducing gum. Water used for syringing must be of the same temperature as the house. Ascertain the condition of inside borders, and where necessary afford a proper supply of water. Disbud very carefully at this early season, removing a few growths daily from a tree preferably to many at distant intervals. The latter practice gives a check to the roots, and promotes wood growth at the expense of the fruit, which for lack of assimilated matter often falls at this juncture in consequence of sap congestion. Maintain the night temperature at 55°, 60° on mild nights, 60° to 65° by day artificially, 5° less on those figures when the weather is severe and dull. Ventilate early, admitting a little air at 65°, not allowing an advance over 70° without full ventilation, closing at 65°, always excepting a small space at the top of the house left constantly; this prevents a vitiated atmosphere, and secures a healthy condition in the leaves, which enables them to do better and more work in the daytime.

Second Early Forced Houses.—Trees started at the beginning of the month are expanding their flowers, and before they open it is well to make a close scrutiny of the trees, and if any aphides are found fumigate to exterminate the pests. Great care is necessary in fumigating, as the organs of fructification are easily and irreparably injured. Moderate fumigation or vapourisation on two or three consecutive evenings will be sufficient, for keeping insects in check until the fruit is set. Where there

is an excess of blossom buds draw the hand the contrary way of the growth along the under side of the trellis or its back so as to remove those there situated, thinning elsewhere with the fingers, leaving the best situated. Syringing must cease when the buds show colour; but damp the house in the morning and early afternoon, always avoiding a stagnant atmosphere. See that inside borders are thoroughly moistened through to the drainage, but avoid needless waterings.

Succession and Late Houses.—Finish pruning the trees at once, dressing them with an approved insecticide, many excellent kinds being advertised; and secure the trees to the trellis, always allowing ample space for the swelling of the branches, and leave room between them for laying-in young wood for future bearing. Fork the border lightly, not disturbing the roots; and after removing the loose soil, supplying fresh in its place, dress with a sustaining fertiliser, such as the following mixture:—Dissolved bones, dry and crumbly, three parts; double sulphate of potash and magnesia, two parts; and air-slaked best chalk lime, one part, mixed, using 4 ozs. per square yard, and scratch in lightly with a fork. If the borders are at all dry they should be given a thorough supply of water. Ventilate to the fullest extent, except when frost prevails; even then frost will not do any harm until the buds show colour. Houses with the roof-lights off need not have them replaced until starting time, or to insure safety for the blossoms.

THE KITCHEN GARDEN.

Forcing Carrots and Radishes.—Carrots are easily forced, and the roots in a young state form an excellent dish. A mild hotbed surmounted by a shallow frame or placed in a shallow pit is an essential. Cover this with about 6 inches of fine sandy soil in which to sow the seeds. The early stump-rooted or Forcing Horn Carrots are the best for the purpose, and the seed may be sown either broadcast or in drills. If broadcast, moisten the soil, if at all dry, and then sow on the surface thinly to obviate any necessity for thinning out. Do not attempt to rake in the seed, but cover with a little fine soil. Should sowing in lines be preferred, open shallow drills from 6 inches to 8 inches apart, the latter distance for Radishes between, water the drills and then sow the seed thinly along them, lightly covering with fine soil. Close the frame and cover heavily with mats till the seed germinates, after which admit all the light possible, and give a little air at the back of the frame during the warmest part of the day, ventilating more freely as the weather gets warmer and the plants increase in size. A similar system may be advantageously adopted with Radishes.

Carrots and Radishes in Rough Frames.—Profitable early crops of Carrots and Radishes can be grown without the aid of glazed lights. Rough frames can be easily constructed, and these can be made either deep enough to hold a depth of about 2 feet of manure, or manure and leaves, or they may be shallow and rest on the top of a hotbed. Canvas-covered frames, straw mats, or ordinary Russian mats are all suitable for covering and protecting. Prepare the seed bed and sow the seeds as is advised in the preceding paragraphs.

Radishes in the Open.—Should the weather keep mild the market growers' plan of sowing early Radishes in the open is worthy of imitation. Prepare a sunny slope by manuring heavily, and on this sow the seed somewhat freely in beds. Cover with strawy litter from which the manure has been separated, lightening this up occasionally with a fork. When the plants are up carefully remove the litter on mild days, returning it by way of protection in the evening. This small amount of labour is frequently rewarded by heavy and very remunerative crops of Radishes.

Forcing Potatoes.—Pot culture is seldom satisfactory, the crops resulting being light. Those who care to try this method of securing early dishes should half fill 9-inch pots with light moderately rich soil, and place one good-sized previously sprouted tuber of a short-topped early variety in each, or if 10-inch or larger pots are used two tubers may be set in each. Cover with soil, and arrange the pots in a moderately warm position, but hard forcing must not be attempted. When the single primary sprout left to each tuber is well through the surface nearly fill the pots with more of the light rich soil, and keep the pots where sunshine and air can reach them. Avoid saturating the soil at the outset, and also after top-dressing, but when the Potatoes are well in leaf they should have abundance of water, also soot water, or other liquid manure.

Potatoes in Frames.—Pits and frames are most often devoted to the production of early Potatoes. The former should be moderately deep, as the haulm requires a fair amount of head room. Bottom heat is needed, but this ought not to be of a dry or rank nature. If stable manure be used, it should be sweetened and moderated by previous fermentation and turnings of the heap, and is improved by the free addition of Oak or other leaves. A hotbed for Potatoes may be 3 feet deep at the back and 30 inches in front, putting it together firmly. If there is no likelihood of its becoming very hot, cover with about 9 inches of light moderately rich soil at once, and when this is well warmed through plant the Potatoes. Tubers having strong sprouts will be found excellent for this purpose. Drills for them may be 6 inches deep and about 15 inches apart, planting the tubers from 6 inches to 8 inches asunder, covering, and carefully levelling over the soil. Cover the frames or pits with mats every night, and heavily when the weather is frosty.

Early Peas and Beans.—Plants raised under glass and duly turned out in the open produce extra early, if not particularly heavy crops. If the seed is sown now it will germinate without the aid of much heat, and sturdier plants result than would be the case if they were raised in a strong heat. Raise abundance of plants, as they should be planted thickly in the rows. A quart of seed will give enough plants to form a row equal to a length of 90 feet. Sow the seed either somewhat thickly in 4-inch pots,

from which the plants may be moved with their roots undisturbed direct into the ground, or in boxes of light soil, eventually moving the plants in this instance without any soil, but saving the roots intact. If extra early dishes of Broad Beans are required sow seeds of Early Longpod, and treat as advised in the case of Peas.

THE BEE-KEEPER.

THE WEATHER.

BEE-KEEPERS as a body doubtless make observations of the weather more than the ordinary individual, and since my last notes appeared on this subject there have not been many changes to chronicle. We have had fogs, and a few slight frosts, the most severe being on the 23rd, 24th, and 25th of December, when 9°, 10°, and 11° respectively were registered. But generally speaking the weather has been mild and open. On several occasions the sun has shone brightly during the middle of the day, and bees were flying merrily from all the hives. This will be of benefit to them, as it keeps them in a healthy condition.

It is after cold rain, or a fall of snow, when the ground is exceedingly cold that bees die in great numbers becoming numbed directly they alight on the cold soil, where they become a ready prey for the birds, which are ever on the alert. Bees, if found in great numbers in this condition, may be brought to active life again if they are collected and placed in a box near the fire for a few minutes, and then liberated, when the majority of them will fly home to their various colonies. It is, however, not possible to do this on a large scale, but if attempted, should always be done as early as possible.

The open weather is having an effect on the early spring flowers. Already the Snowdrops, Aconites, Arabis, Primroses, and others are fast coming into bloom. So, whatever the weather may prove to be during the next few months, there has been nothing to complain of in this respect up to the present time.

BEES BREEDING IN WINTER.

Although brood in the hives is not to be encouraged in mid-winter, if healthy strong colonies were examined at the present time there would doubtless be found a patch of brood in two or three of the frames in the middle of the hive. It is not advisable to make an examination at this date, as much harm may be done. If the weather continue favourable the brood will prove of great advantage, as it will help to make the stocks strong.

When bees are provided with sufficient stores early in the autumn, so that no extra food is required during the winter or early spring, they rarely make the mistake of raising too much brood at midwinter. It is when bees are fed artificially, either with candy or in uncapping of sealed stores, that they become unnaturally excited; the weather may be fine and open, food is being supplied freely, but not wisely; the queen becomes excited and commences to lay, and all goes well for a few days. A change comes in the weather—a low temperature prevails, lasting a few days, or it may be weeks; the bees cling more closely to the cluster, and they are not numerous enough to cover the brood. What is the result? The brood becomes chilled, and so will many of the bees in their anxiety not to desert the brood; they succumb, being unable to return to the cluster, and so the last state of that colony is worse than the first.

This is no imagination. Similar cases to the above are being constantly brought to my notice, and should act as a deterrent to those who are inclined to neglect the autumn feeding (when necessary) of their bees, and relying on candy or something similar in winter instead. If the latter is given to the bees in reason at this season all will be well, but care must always be taken not to unduly excite the bees during the dark dull days of winter, or mischief will be done.

If the weather does not come unduly severe those stocks in warm hives with ample natural stores will continue breeding from this time onwards, and those are the colonies that will undoubtedly give the best account of themselves during the next honey harvest.

ENEMIES OF BEES.

Bees being constantly on the wing during fine weather, it is advisable to be on the look out for their enemies, and the worst culprit that I have to contend with in this respect is the different species of tits, the chief among them being the great tit (*Parus major*). If these pests were satisfied with being scavengers in picking up only the dead bees they would be welcomed as friends, but when they take them whilst on the wing, and when the temperature is too low for them to leave their hives, they pounce down on to the alighting board and tap at the entrance with their beaks so as to tempt some of the most venturesome of the bees to leave their hives, which they

invariably do by coming to the entrance to see what is the matter, when they are immediately seized by the tit and taken to the nearest tree and dissected. They repeat the operation continually. Very interesting to the on-looker, but rather trying to the nerves of the bee-keeper.

It is necessary to preserve the lives of as many of the bees as possible, so the tits are trapped with a small mouse trap baited with a piece of bread or meat, by which means they are readily taken. Tits are very numerous in the district, owing to the great expanse of woods near my apiary; so much is this the case that fifty of these birds are sometimes caught in a fortnight.

Sparrows are sometimes troublesome, but not to any serious extent; they usually catch the bees whilst on the wing. Mice are also troublesome, and may be caught by the same means. If mice once gain an entrance to a hive at this season they will soon destroy the combs and honey, and the bees will collapse. It is, therefore, an advantage to always have a few traps baited and placed near the hives throughout the winter months.—AN ENGLISH BEE-KEEPER.

A PROMISE FULFILLED.

ON page 21 "A Yorkshire Man" reminds me of a promise I made in this Journal some months ago, that, large and small hives should be tested in this district and the results made known. I am pleased to tell "A Yorkshire Man" that a careful test, both in my apiary and in others, proves large hives far in advance of those containing ten standard frames. In an apiary, about six miles from my home, containing a mixture of standard hives and hives containing twelve frames 18 by 8½ inches deep, and those containing twelve frames 20 inches by 8½ deep in each case, the large hives nearly doubled those of standard size in the surplus taken.

"A Yorkshire Man" says it would be interesting to know if I had reached the 350 lbs. mentioned in this Journal some time ago. To be candid, I have not; but I am pleased to tell "A Yorkshire Man" that 180 lbs. have been reached—that I consider fair for the past season, as there is no White Clover sown for sheep pasture within two miles of my apiary. But Mr. Lancelot Quayle, Isle of Man, took 334 lbs. from one hive. If the test mentioned above had been in one apiary only, there might have been room for doubt; but when apiaries from one mile to six miles apart in the hands of different men give the same results, it is clear the large hives are in predominance in this district.

Lest the readers of this Journal think I have had no experience with hives with standard frames, I may tell them I have over a score of such, and ten years ago it was my favourite hive. My best standard hive gave me nearly 70 lbs. of surplus last season, but required feeding, while my large hives required no feeding. This Journal opened my eyes as to the advisability of using large hives, and having tried the principle I have no desire to turn back. If "A Yorkshire Man" will pay me a visit in June (if not far away), I shall be pleased to see him; then he can have a peep into the hives, and then they will be able to speak for themselves.—GEORGE HOWDENSHERE.

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

The Weather Plant (G.).—Though this plant is not commonly offered in catalogues, we do not think you will have much difficulty in procuring seeds. Firms of repute such as Veitch's, Barr's, Sutton's, or Carter's, would be almost certain to supply it.

Position for Vine Border (A. B.).—We presume your object is to train the Vines up one side of the roof and down the other of the span-roof house which stands east and west. This can very well be done. Have the outside border on the south side. You do not ask for information on making the border. If you need any read carefully the sound article of "Vitis" (who is an accomplished Grape grower) on page 617 of our issue of December 30th, 1897.

Holboellia latifolia (J. P., Devon).—The fruit sent is that of Holboellia (or Stauntonia) latifolia, a Berberidaceous plant, introduced from Nepaul in 1816. Hardy against walls in the South of England. The fruits, which have a general resemblance to those of Passiflora edulis, are eaten by the natives of Nepaul. The pulp is sweetish, yet more or less insipid. Those of Stauntonia hexaphylla are eaten in Japan, and the juice is also applied in cases of ophthalmia.

"Mites" on Vine Roots (T. P.).—Your Vines may possibly be suffering from an attack of Phylloxera. We cannot tell which without examining specimens of the fibrous roots to which you refer. Please search for and send specimens packed in damp moss in a small strong box on Friday or Monday next, so that they may not rest over Sunday in the Post Office. Many fragile paper boxes reach us in a smashed or flattened state; we ask that the one you use may not be of that character.

Propagating Variegated Aucubas (A. G. G.).—Healthy, short-jointed branchlets from 9 inches to a foot in length, more than half divested of leaves, deeply and firmly inserted in sandy soil, in a cool frame in September, kept close and shaded for a time, emit roots freely. We have seen many plants raised by inserting such cuttings in the open ground on the north side of a wall in August, sprinkling them occasionally if the weather be dry. They would root even now outside if the present mild weather continue, which, however, cannot be expected. The cuttings may also be rooted at this time of the year in pots in a warm pit or propagating case, the pots being plunged in gentle bottom heat.

Planting Box (G. A. B.).—In planting Box for edgings it is essential that the ground be made very firm and quite level, then stretch the line, keeping it firm with pegs, and take out a trench, the side next the line being perpendicular; arrange the slips in it close together and level, holding them in position with one hand while the soil is beaten firmly against them with the other, then fill in with the rake or spade, and tread the ground along both sides the row, which, when completed, may be 2 inches above the walk. If no rooted portions can be had it will be well to take off a number of rootless slips and lay them thickly and deeply in the ground in a position shaded from the sun in summer, and they will emit roots and be ready for planting in the autumn. Rooted portions may be planted now if the weather is favourable, or in the spring, the earlier the better.

Stocks for Roses and Fruit Trees (New Reader).—The Manetti stock is an Italian Briar of very free growth, hardy in this country, and increased by cuttings inserted in the open ground in the autumn. English Briar stocks for dwarf Roses are raised in the same way, also from seed. Before the cuttings are inserted the buds are carefully removed except two or three at the top of each cutting, these alone being above ground. The cuttings are inserted slantingly in ridges, and when the stocks are large enough for budding the soil is levelled down and the buds inserted close to the ground, one in each stem, below the branching growths. Quince stocks are raised from cuttings on the same lines as described for Briars, also by layers. Pear and Crab stocks are obtained from pips or seeds of those fruits sown in the open ground. Many stocks for Apples, and known as "free" stocks, are raised from Apple pips obtained in the process of cider making. Paradise stocks are raised both by layers and cuttings of dwarf precocious kinds of Apples, which are grown for that purpose. They are not employed for Pears, but only for providing Apple trees of compact growth and early productiveness.

Making Grafting Wax (Amateur).—Several kinds require to be used warm, one of the simplest being equal parts of yellow wax and resin melted together and applied when cool enough. The following has not the inconvenience of requiring to be applied warm, and may be prepared and used without being heated:—Yellow wax 1 lb., turpentine 1 lb., Burgundy pitch 8 ozs., mutton suet 4 ozs. Mix all together, and mix thoroughly, and leave them to cool. Form the mass into small balls, as it will not stick to the fingers, and use them when opportunity offers. Liquid grafting wax is a very useful application, and is, perhaps, the most convenient for the purpose of all the mastics used for covering wounds and grafting. It is of the consistency of varnish, and is applied very thinly with a brush. Care must be taken not to lay it on thickly, for the surface hardens so rapidly the alcohol is prevented evaporating. Resin 1 lb., beef tallow 1 oz., spirits of turpentine one tablespoonful, alcohol (95 per cent.) 6 ozs. Melt the resin over a slow fire, when melted take it off and add the beef tallow, stirring it constantly; let it cool somewhat, mix the spirits of turpentine little by little with it, and at last the alcohol in the same way. Should the alcohol be added while the mass is too hot, much will be lost by rapid evaporation; if, on the contrary, it is too cool, it will form a viscid lump, and must be slightly heated again. Stirring briskly is indispensable to mix the ingredients thoroughly. In well-corked bottles it keeps for years. If in course of time it becomes too thick, the addition of some alcohol will make it liquid again. For this purpose it must always be warmed. It is a good plan to put the bottle containing it in boiling or hot water to accomplish this.

Grafting Aralias (*Twenty-five Years Subscriber*).—We have not heard that the elegant *Aralia Veitchii* is increased by grafting on *A. Sieboldii*, now called *Fatsia japonica*; but we know that many plants are established by grafting on stocks of *A. reticulata*, raised from cuttings of ripe, healthy wood, which root freely in gentle heat, while those of *A. Veitchii* do not. The stocks are established in small pots, the stems cut down to within an inch or two of the soil, and the scions 2 or 3 inches long, neatly attached by splice or cleft grafting, made secure, and air excluded by grafting wax. The pots are plunged in cocoa-nut fibre refuse in a close case or under a hand-light, in a temperature of 70° to 75°, and gentle bottom heat is advantageous. Possibly the scions might "take" on young stocks of *Fatsia*, or on pieces of root with fibre attached, though we have not seen *A. Veitchii* so increased; but we have seen hundreds of plants established on the narrow-leaved *A. reticulata*. *A. Scheffleri*, a New Zealand species, is also said to be suitable for the same purpose.

Gas Liquor (*H. J. B.*).—This must be used very carefully, and highly diluted with water. For vegetables it may be used at strengths corresponding to the vigour of the plants, about 1 pint to a 3-gallon water-potful of water being quite strong enough when it is used over the foliage, and in some cases it will brown the plants at that ratio, not only because the foliage differs in hardness, but through the variability of the strength of the gas liquor. For pouring between the rows of growing crops it need only be diluted with six times the quantity of water, and is valuable for all the Brassica tribe and Peas, taking care not to apply it to their stems. For fruit trees it should be diluted with ten times the quantity of water, and be applied during the swelling of their crops, preferably in the first half of their swelling, as given late it has a tendency to induce late growths. It will benefit every kind of plant that needs support, only take care to supply it weak, and to pour it clear of their foliage. It, however, requires to be used with care, as an overdose is fatal.

Poinsettias Losing their Leaves (*J. H.*).—The leaves always turn yellow and drop off after the plants have been in beauty for some time; but the change and casting of the foliage is accelerated by the checks the plants have received by sudden changes of temperature or extreme dryness of the roots even if only for a few hours. Continue watering them regularly as long as the bracts remain fresh and bright, then gradually withhold water until the soil is quite dry. After a few weeks of rest the plants may be cut down, the growths being made into cuttings and inserted in sand, one joint below and one eye just above the surface. If the pots are placed in heat these cuttings will emit roots, and with good culture form fine plants during the season; cuttings of the young shoots (that are produced if the plants are not cut down) root freely if inserted when 3 inches long and placed in brisk moist heat and shaded so as to prevent flagging. The old cut-down plants, when they have made half an inch of fresh growth, should be shaken out of the pots and be repotted in fresh soil, and if properly treated they will produce large heads of brilliant bracts by next Christmas.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. *Dessert Pears cannot be named in a hard green state.* (*A. R.*).—The Apple is not the short-stalked *Hanwell Souring*, nor are we quite sure what it is. It possesses most of the characters of Dutch Mignonne, but in quality is not equal to that variety in its normal state. (*D. E. H.*).—1, Northern Greening; 2, a local seedling; the Pear is Brown Beurré.

Names of Plants.—We only undertake to name *species* of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*F. F.*).—1, *Selaginella Kraussiana variegata*; 2, *Adiantum pubescens*; 3, *Maxillaria nigrescens*; 4, *Selaginella Martensi*. (*E. M. E.*).—1, *Odontoglossum Cervantesi decorum*; 2, a good form of *Sophronis grandiflora*; 3, *Masdevallia polysticha*; 4, *Lælia anceps*, poor variety; 5, *Selaginella cæsia*; 6, *S. involvens*. (*I. F. E.*).—1, *Asplenium cicutarium*; 2, *Lomaria discolor*; 3, *Cypripedium venustum*. (*C. O. P.*).—1, *Cypripedium insigne Maulei*; 2, *Lælia anceps*. (*P. J. R.*).—1, *Adiantum gracillimum*; 2, *Nephrolepis exaltata*; 3, *Asplenium bulbiferum*; 4, *Pteris serrulata*; 5, *P. cretica*; 6, *P. serrulata cristata*.

HOW THE MONEY GOES.

HAVING now got fairly into the swing of the work it would be well to inquire how the money allowed by Government to forward technical education in this country is being spent.

We have lately read of much good work being done on the Continent, particularly in the countries of Denmark, Norway and Sweden, and the question suggesting itself is this: Is Government doing as much for us in the way of education (technical) as these countries are doing for their people? We may take that question in two ways. First, Having now waked up to the fact of our great deficiencies, as compared to the rest of the continental countries, we are trying by great efforts to retrieve our past—i.e., that is by providing teachers and appliances. Secondly, we are rather defeating our own ends by our costly methods, and we do not attract the right sort of people for the training. We are helping to educate many who are in a position to educate themselves, and we only touch as it were the edge of the masses. As far as we can learn by reading, Sweden

is particularly fortunate in her class of pupils. She gets hold of the horny-handed sons of toil (and the daughters too), and gives them such help as will enable them to become scientific workers, each in his own sphere, and thus in the end, by practical object lessons, proving the best of teachers. Of course, we are now referring to matters purely agricultural.

We English are so fond of bricks and mortar. We like palatial residences, fine offices. We build for the future; but laudable as this may be, is there not a danger that we overdo the thing? Building operations are costly, they involve a large expenditure of capital, and it is a question as to whether the money can be really afforded.

Grand homes and model buildings are all very well for the pupil who comes of rich parents, but how about the small farmer or bailiff's sons? Will they not be rather out of love with their home surroundings? Perhaps this is a healthy form of discontent, but would not they be better fitted for their future work if they had not found everything made ready to their hand? We must bear in mind these poorer pupils will still be the employed, not the employers.

We will now turn to a few figures. We know figures are dull reading, but if carefully studied they convey concise information. Out of the sum of £588,000 spent on technical education, £78,000 was used in the various counties for instruction in agriculture—this is only about one-seventh of the whole; and it hardly seems fair, as in all the large centres of population technical work has received much attention in the past.

Nearly all the counties spend a considerable part of their grant in dairy work, either by the establishment and maintenance of dairy institutes, by a series of dairy classes (itinerant), or by providing money for scholarships at some of the many dairy institutes. It is interesting to read how the various counties apply their share of money. Buckinghamshire receives in gross the sum of £3794 for technical work, and out of that sum only a paltry £626 is applied exclusively to agriculture. Gloucestershire receives £13,000, and spends £540; part of this goes to pay an agricultural adviser. What that implies we hardly know, for a man of any talent would, we think, require the whole of the £540, but perhaps he is only an expert in one branch.

Does London, with her manifold advantages, require the £172,000 which falls to her share, and Middlesex takes £21,900? One would have thought that London's share might have included Middlesex. Some of the essentially agricultural counties must stand in need of a part of this great sum. £500 is spent in Northamptonshire principally on lectures. Well, unless the lectures are followed by examinations, or inspections of actual work, we doubt the good done is but fleeting. We are glad to see a certain amount of aid given to the brother science—viz., horticulture.

Northumberland having established an Agricultural College, naturally devotes a large portion of her share to the maintenance of that College, and most of us have heard of the Dairy Institute, near Nottingham, under Mr. Benson, which is doing such a good work, and which rightly absorbs a good deal of the Notts share. A splendidly equipped College is also provided at Wye for Kent and Surrey, and presumably much help is given to harassed Hop growers. Surrey is also well in advance—the pioneer county in teaching the young (the men of the future) by theoretical lessons in evening schools and practical lessons on the land—a hopeful combination. The amount for horticulture in the whole country is £8000, and no one will be surprised to hear that Kent takes the lion's share.

So much has been said on the poultry question, that if at any rate we sin now it is our own fault, for some of the best teachers that the country has ever produced are lecturing up and down the land.

Veterinary classes are popular, and do a good work when the lectures are delivered by the right men; by that, we mean men who impart knowledge in a pleasing and satisfactory manner. Devon rejoices in securing the services of an enthusiastic botanical agriculturist—a man with a great and deep knowledge of manures and their uses. His services, we believe, are given freely to the farmers who ask for and require them.

We are not always sure that the best instructors get into the country districts. It is often thought that anything will do for Hodge and his masters. Never was a greater mistake made. Cheap prosy men, however able to handle the spade or the plough, and dry didactic scientists cannot evoke interest and gain sympathetic response. The greater the need, the greater should be the care taken in selecting suitable and able men. That is where real genius comes in. A clever man can adapt himself so well to his audience; a second-class man not only loses his own head when faced by apparent stupidity, but also brings discredit on the cause that he advocates, and a succeeding lecturer must free the minds of his hearers from prejudice before ever he can hope to secure a hearing.

The scheme of technical instruction is yet in its infancy. We are now finding out the weak points in the system, and the thing will gradually right itself.

It is hard work teaching the middle-aged, and possibly, in the long run, that portion of money used in training the young and for the encouragement of the various agricultural seats of learning will be found to have been the best expended.

Note.—During the last year France voted £688,000, Germany £502,000, U.S. America £343,000, Great Britain £78,000! for agricultural instruction.

WORK ON THE HOME FARM.

With all the lea intended for Oats satisfactorily ploughed, and fallows not quite ready for working—or, rather, the season for such work having hardly yet arrived—we have to look for catch work to keep our horses in employment and health.

Grass land will always show a good return for the labour of carting road scrapings, or anything of like nature that can be had for the fetching. The highway authorities are usually only too glad to have any ridges by the side of the highways ploughed up and carted away, and will often find hands to fill the carts. Where limestone or slag has been used on the roads, the roadside refuse contains a considerable per-centage of lime, and will be found to encourage the growth of Clover in grass land. It should be well spread, and then chain-harrowed at once to insure evenness of distribution.

Turnips have almost outgrown their best qualities; we mean they have attained a size which not only is against their chances of resisting frost, but which makes them distinctly less valuable as food. We like large Turnips for autumn consumption, and Swedes can seldom be too large; but to stand a reasonable amount of frost and then be suitable food for the breeding flock, the size of the roots is strictly limited. For the use above mentioned we sow a little later and omit the close singling. We have found a cluster of three or four roots small in size much more hardy and useful than one large one after the new year has come in.

Though not advocating the extensive use of Turnips for ewes in autumn, we think that they may be freely given now until lambing commences; but always a due proportion of dry food must be given with them.

Now that cakes are so much dearer, dried grains or malt culms are desirable foods for ewes on account of their price as well as their dry nature, and are particularly good where grass is scarce and the sheep must be kept altogether on Turnips. A valuable manurial residue is left after the consumption of either of these foods.

CHRYSANTHEMUMS UP TO DATE.

ONCE more I have the pleasure of placing before the readers of the *Journal of Horticulture* the results of an election of Japanese and incurved Chrysanthemums, carried out by leading growers and exhibitors of this flower in various parts of the kingdom.

The election in 1894, 1895 and 1896, I am convinced, was useful to many persons, especially those who were taking up the cultivation of this flower for the first time, in assisting them to make selections, which is now admittedly a difficult matter, seeing at what rate new varieties are introduced in the chief sections.

The publication of the results, I have reason to know, has interested many who are not actually cultivators. The election carried out in 1896 was managed upon a different principle from the present or any former one. The country was divided into centres, a leading cultivator taking charge of his particular district, obtaining the returns, and sending them in tabulated. By this method, no less than 107 persons took part in the election.

This year we have gone back to our original plan of inviting none but persons of experience to send in returns compiled by themselves. In the former case some electors, owing to their inability to visit the larger exhibitions, had not the same opportunities as others, although equally qualified in other respects. There is no disguising the fact that those persons who do visit, many, or even a few of the many first-class exhibitions in various parts of the country, are in a much better position to give an opinion upon the relative merits of varieties so numerous offered to the public. Especially is this the case now that new sorts are increased so rapidly, and many of them rushed into the market before they are sufficiently tested to prove not exactly their worth, but to what section they belong. It is under such circumstances that the annual election has been found of so much service to beginners.

Where a large number of persons take part in the selection who have not been able to personally examine many of the newer varieties, their

opinions, although they may be of value, tend to somewhat dilute those who are better favoured in having had such varieties placed before them. In making these remarks upon this portion of the subject I cast no reflection upon the ability of those who may have assisted in a previous election, but take the present opportunity of explaining why the difference in the number of electors is so great, comparing the thirty-three of the present election with the 107 of the last. Invitations in the present case numbered thirty-seven, and thirty-three sent lists in time for compilation. I desire to thank all those who so heartily co-operated in obtaining the returns—work which was sincerely entered upon and, I am sure, much enjoyed by all. To Mr. James Threlfall, my assistant, thanks are equally due for services cheerfully rendered in tabulating the returns so carefully and accurately.

A few remarks upon the position of certain varieties and the result of the election may not be out of place.

Dealing first with the Japanese section, as being more popular than the incurved, I find that in the selections of fifty varieties the thirty-two electors (one who is a noted grower of incurved did not feel qualified to include the Japanese) sent in 190 names, showing how diverse are the opinions amongst experts as to which varieties are really the best. At the last election 258 varieties were named by the 105 electors, proving that the greater the number of electors the greater the divergency of opinion. In the year 1895 sixty-nine electors named 187 varieties in the selection of thirty-six. In the election the year previous, in obtaining the names of the best twenty-four, ninety-three varieties were given by the forty-six electors.

In the present instance no fewer than fifty-nine names of varieties are given once; nineteen are mentioned twice; while twelve others receive three votes each. These figures reduce the number of varieties down to exactly 100, which really is not a very wide range to select fifty from. The reduction of the numbers in this way shows that there is a greater concentration upon the really improved varieties than has occurred before.

Even a cursory glance at the selected fifty will show that electors of experience have made their choice with due regard to the quality of the flowers, and not merely for their size. The bulk of the fifty are noted for an improvement in form coupled with a good mixture of colour. If we except *Etoile de Lyon*, *Mrs. C. H. Payne*, and *International* it would require a stretch of prejudice to say that the list contains varieties which are coarse or lack refinement.

In the present election no less than seven varieties tie for the premier position. It would be difficult indeed to say which of the seven is entitled to the first place on the list. In the 1895 election three varieties tied for this distinction. In the year previous the same number were bracketed, while in 1896 four earned the distinction. It cannot be other than pleasing to Mr. Cannell and myself to find the variety bearing my name occupying so high a position after being cultivated twelve years. No other variety in the first fifty can claim more than seven years' service, this being *Vivian Morel*. *Sunflower*, which occupied such a high position as tenth on the list in 1896, has now fallen so low in the estimation of electors that it only receives two votes in the present list. Take again *Stanstead White*, which was tenth on the list in the 1894 election, and now only receives a single vote. Even that charming variety *Mlle. Thérèse Rey*, which was only four votes behind the premier in 1896, now fails to find more than seventeen supporters.

It cannot be said that the hairy varieties are popular with the electors. Not a single one is to be found in the first fifty. Even *Hairy Wonder*, which is the best of the type, gets no more than ten votes, while *Mrs. Alpheus Hardy*, the pioneer of the section, is not once named.

Those persons who are partial to the Japanese incurved, of which I class *Robert Owen* as a typical variety, have not much cause for satisfaction, as with the exception of *Australie*, *Oceana*, *Modesto*, *Lady Byron*, *Western King*, and *Sunstone* the section is poorly represented. Even *Robert Owen* fails to obtain more than eight

votes. *Viscountess Hambledon*, a charming variety when seen in proper character, receives support from only seven electors.

Cultivators and lovers of *Chrysanthemums* generally appear to favour varieties of the type of *floret* of *Madame Carnot*, *Mutual Friend*, *Phœbus*, *Mons. Hoste*, *Simplicity*, and *Vivian Morel*. He indeed would be a bold person who would say these are not of a desirable type to encourage. All possess the characteristics of depth of *floret* as well as width of bloom. The *Meg Merriès* type of bloom is not so much in request nowadays, and fortunately, as it was some years ago.

A few brief extracts from letters received, showing the opinion in which the election is held by various electors, will be a fitting conclusion to these rather longer notes than I at first intended them to be.

Mr. J. Dumble, *Picton Castle Gardens*, *Haverfordwest*, writes:—"I am very glad you are again publishing the lists. I am sure they serve a most useful purpose, and I am also sure your labours are appreciated."

Mr. R. Jones, *Barford Hill Gardens*, *Warwick*, says:—"It will be interesting to compare the 1896 lists with those of 1893, as many in the former must make room for newer introductions."

Mr. Folkard, *Sand Hutton Hall Gardens*, *York*, writes:—"With so many new Japanese introduced each year it is difficult to know which to choose for the best. I wish you every success."

Mr. C. J. Salter, *Woodhatch Gardens*, *Reigate*, says:—"I have pleasure in forwarding list. It is a difficult matter to place the incurved varieties. The so-called incurved, such as *Ma Perfection*, *Lady Isabel*, and *Duchess of Fife*, must take a high position in the list, owing to their size. In my opinion they should be relegated to the Japanese incurved class. By all means have classes for Japanese incurved."

Mr. A. Sturt, *Round Oak*, *Englefield Green*, *Ascot*, writes:—"I am pleased to see you are again at work in endeavouring to obtain from growers the best varieties for exhibition, and also those of recent introduction."

Mr. A. Haggart, *Moor Park Gardens*, *Ludlow*, says:—"I am very pleased to comply with your wish re selection of Japanese *Chrysanthemums*, and the results must be very serviceable."—EDWIN MOLYNEUX.

[We wish to thank most cordially Mr. Molyneux and all who have aided him in carrying out the object in view—namely, the determination by experts and skilled cultivators of the best present-day *Chrysanthemums* for exhibition, including those of the newer varieties which have been sufficiently tested for an unprejudiced opinion to be formed on their merits. We should like for all new varieties of promise to be tested by the greatest possible number of growers, in order that a full and fair estimate may be obtained of their merits in the autumn.

We take all responsibility for placing Mr. Molyneux's patronymic at the head of the list of what may be termed maximum equals. We think it entitled to the position on the ground of seniority, apart from the fact that no decided improvement on it has yet been produced in its own distinct and brilliant character. We must watch the development of *Joseph Chamberlain*—a progressive name.

Comments on the selected eighteen new Japanese varieties and thirty-six incurved varieties will follow with the tabulated lists another week.—ED.]

(To be continued.)

LAWNS.

THE alternating smiles and tears of our much-abused climate may be credited with the fostering of a feature of paramount importance to picturesque gardening. This in allusion to our lawns which, whether they be according to scale but little more than the grass plat on the one hand, or stretch into bold sweeps measured by acres on the other, strike the keynote of a harmony we islanders have become so accustomed to as a matter of course, that but few, perhaps, fully recognise how much is owing to this grand feature.

Yet, as there are gardens and gardens, so are there lawns and lawns, good, bad, and indifferent; but none so bad, even under their most impoverished forms, as not to contribute in some degree to one of the chief characteristics of British landscape gardening. How much more, then, must this be the case where the cultivation of the best Grasses adapted to the purpose is intelligently carried out, and the keeping is all that could be desired! It is, perhaps, only during an exceptional season of drought that signs of neglect from sins of omission become fully apparent, and the lawn, which has been so persistently shaven and shorn for years, with never a thought of any return being made, becomes an arid waste until the kindly rain restores its half-hearted vigour.

Were there anything wanting to emphasise the importance of this phase of gardening, for such, I think, it may be reasonably termed, it is probably to be found in the high esteem afforded to it by more impartial observers. Some transatlantic cousins when "doing" one of our historic Universities with all its time-honoured associations, were asked what particular feature had impressed them most. The reply was, "We guess it is your grass." Hence we may see at a glance the beauty of our English lawns as others see it. Most have, perhaps, come to regard this subject as one being exclusively a part and parcel of the ornamental grounds in direct connection with or contiguity of a mansion. This is, indeed, the principal feature with which we have now to deal, but in the landscape gardeners' art no such restriction is implied.

So far back as 1776, Arthur Young in his descriptive notes ("Young's Tour in Ireland," vol. i., page 23), speaking of the Duke of Leinster's seat, says, "The park ranks among the finest in Ireland, it is a vast lawn." And again, "The park spreads on every side in fine sheets of lawn." Only in one way can this be viewed in direct relation to our subject, and that is, literally, from the garden front of the grand old limestone mansion; and, in spite of many alterations which have taken place since Young visited Carton, the same vantage point in all probability occasioned his critical remarks, it being an excellent example of that happy blending of the kept grounds and a mile of unbroken stretch beyond to where unbrageous plantations and a background of distant mountains complete the scene.

The importance of pressing into service a wide, or rather deep stretch of greensward in the picturesque treatment of grounds surrounding a mansion, connected by the invisible link of a sunk fence, can hardly be over-estimated, although the style and size of the building are considerations not to be ignored, for instances may be noted, although but rarely, in which undue amplitude of unbroken space dwarfs the residence it is intended to dignify; particularly is this the case with some old Tudor mansions. The error, however, is more often one of foreshortening where ample margin is afforded for bolder treatment.

With what may be termed the lawn proper, and which is of more immediate concern, it is easier to point evils than apply remedies, for many a man at the head of affairs has perforce of circumstances to follow the routine of mowing, rolling, and sweeping with but little more than a passing thought of those thorough measures conducive to the best results. I cannot regard the now indispensable lawn-mower as an unmixed blessing, for from long observation the conclusion has been deduced that its persistent use promotes the growth of Daisies, to the detriment of the grass. So much so was the case in one particular place, that, to perpetrate a "bull," our grass was all Daisies in the early summer months. In this case distinct advantages were noticeable whenever an opportunity offered of letting the grass get well ahead, and resorting to the scythe when it was again necessary to have all things decent and in order.

In another place where local conditions altered cases, and during winter, and well on into spring, our grass was all moss, whilst little or no improvement was gained by the usual superficial remedies; a liberal surplus of superphosphate of lime over and above what was required for some old pastures led to a trial of it on the lawn, on the lines that what is sauce for the goose is sauce for the gander. Fortunately the family were absent for some considerable time, for a somewhat liberal dressing, in the words of an old workman, burnt everything up; but, practically, as everything visible was moss, and the burning was succeeded by the best growth of grass that had been seen for years, it was "All's well that ends well," and worthy of note. Further trials showed the superiority of superphosphate over fresh slaked lime for the purpose.

WILLIAMS' MEMORIAL. — At a recent meeting of the Williams' Memorial Trustees, Dr. Masters in the chair, it was decided to offer two silver Memorial medals at the summer show of the Royal Botanic Society, to be held in May, and two silver Memorial medals at the York Gala to be held this year.

In renovating and re-levelling some old tennis lawns at a minimum of expense and labour, the same turf was relaid upon a top-dressing of fresh soil, the action of cutting the sods being sufficient to kill off the coarse weeds which had hitherto been conspicuous. Various kinds of chemical manures have been employed in the endeavour to re-vitalise exhausted lawns in the simplest manner, but the virtues of superphosphate of lime have for the purpose surpassed them all; such at least is the experience and opinion of—A WORKER.

COMBATING EELWORMS AND SUPPORTING PLANTS.

PRACTICE WITH SOLUBLE PHENYLE.

SOME of my friends remember, and not unfrequently make allusions to, some experiments I once conducted in the direction of feeding Grape Vines "through the bottle." Large glass open-necked jars or bottles filled with water were suspended close up to joints from which bunch-bearing laterals sprang. Moss was packed somewhat tightly about the joints and between the tops of the bottles, capillary attraction doing the rest. As a result of being kept constantly moist roots were quickly pushed out by the rod, and were not long in finding their way down into the bottles. From the long straight roots quickly sprung numerous fibres, the interior of the bottles becoming filled with a network of roots. When the Vine leaves were fully developed, and the days bright and sunny, the water was drawn out of the bottles at an astonishing rate, as much as 3 pints being taken out of one bottle in a single day.

During the time I was content to use clear water only everything went smoothly, but directly feeding with liquid manure was commenced the roots ceased to perform their functions, the majority of the fibres perishing in a few hours. Changing the water, pruning the roots, and starting again with clear water resulted in fresh thickets of fibres forming, and after repeated experiments the conclusion arrived at was that we may easily err in applying manures too strongly to delicate roots. Not only are the latter incapable of absorbing manures of any kind other than in infinitesimal quantities, but they may easily be injured by an overdose.

What has that to do with eelworm destruction? would be a fair question. My reply would be, Much, very much, in my case. Those simple experiments have influenced my views on applying manures or insecticides to the soil ever since. It is not the heavy supplies that do the most good; comparatively light dressings or weak liquid manure, *applied at the right time*, doing far better service without risk of injury to tender roots. No doubt roots confined in water are most susceptible of injury from an overdose of anything, but according to my experience not so very much more so than root fibres confined in small ridges, boxes, or pots of soil. No liquid manure and no disinfectant should be applied when the soil is in a dry state. It is safer and far more effectively given when the soil is just moist.

"Halogen," and any other clever student of chemistry, may laugh at the idea that Little's soluble phenyle contains any appreciable manurial properties, and may go on doing so to their heart's content, so far as I am concerned, but this will not prevent my using it freely—primarily as a remedy for eelworm, but also because it is a good fertiliser. Our row of 1 gallon drums just delivered speak for themselves. If I had neglected to order them my foreman would have refreshed my memory, as he had commenced doing every day we transacted business together. Scientists have done much for us in various ways, but too often they prove either too much or too little. Many of those puny experiments about which we hear so much, and upon which such great expectations have been founded, when put into actual practice not unfrequently prove most disappointing. Nor is this to be wondered at, seeing how much conditions vary.

Not till I saw the effects of wetting some of the Tomato leaves with diluted soluble phenyle did I fully realise how strong the stuff is. If phenyle used at the rate of 1 gallon to 1000 gallons of water will injure foliage, then the same strength may, though not necessarily so, be equally injurious to tender root fibres. The quantity used for either Tomatoes or Cucumbers has been gradually reduced until by fair testing we decided that 1 gallon of phenyle is enough for 2000 gallons of water, and that is the rate at which it will be used, as a rule, this season. We certainly applied it very much stronger to the Cyclamens, owing to the eelworm having become strongly established in their roots before we were aware what was wrong. In this instance it was a case of kill or cure. It answered well, but I ought to have added that when root-fibres, instead of a few swollen roots were becoming abundant, the phenyle was applied in a much more diluted state.

Each season we have forked into the surface of newly dug borders intended for Tomatoes a dressing of either kainit 4 ozs., superphosphate 4 ozs., and soot about 8 ozs. per square yard; or 4 ozs. of kainit, 8 ozs. of basic slag, and 8 ozs. of soot. These dressings are

supplemented by frequent waterings with clear soot water and nitrate of soda dissolved, and used at the rate of quarter of an ounce to a gallon of water occasionally. Solid manure is mixed with the second spit at the rate of about a cartload to 4 rods of ground—not a heavy dressing by any means, but just enough to supply the needful humus. The natural and artificial manures, coupled with abundance of water, appear to suit Tomatoes, the plants forming stout hard stems and a fairly disease-resisting growth, but cannot be depended upon to destroy eelworms.

We now, in addition to the natural and artificial manures named, give a good soaking with phenyle when the plants are about 2 feet high and well set with fruit by way of a preventive, and on the first signs of drooping, whether from eelworm or an attack of fungus, a second dose of phenyle is applied. Altogether the plants in all the houses, whether they are in pots or planted out, get a phenyle watering about six times in a season, and if at the end of 1898 we can say our failures were no more numerous than in the two preceding years, then the £2, or rather more, spent on Little's soluble phenyle (bought in quantities at 6s. 6d. per gallon drum) will have proved a good investment.

As I have previously asserted, dryness at the roots is not only most injurious to Tomato and Cucumber plants, especially when these are carrying heavy crops, but it also favours the increase of eelworms. It is along the pathways that the most failures with Tomatoes are likely to occur, because it is there where they are most liable to suffer from dryness. The paths ought to be mulched more heavily than the rest of the borders, and also loosened with a fork occasionally. Cucumbers show the effect of dryness at the roots more quickly than do Tomatoes in borders, owing to their limited rooting area, and the roots are also more easily injured by an overdose of phenyle, or a dressing of chemical or too strong liquid manure.

We use phenyle as a preventive of eelworm, and if the plants subsequently commence flagging from an attack, an application of it saves the greater portion. So tenacious of life, however, is this fearful pest, that we have not succeeded in wholly clearing plants and the soil of it, but if successful in keeping the plants in a profitable condition through several months that satisfies me.

There is nothing gained by keeping Cucumber plants about a whole season, and I prefer to have a quick heavy crop, and then plant afresh. When our first batch was turned out last season, many of them were affected by eelworm. Wholly changing the soil in a house 120 feet long meant much labour at a busy time. Instead of this the old soil was levelled, well soaked with diluted phenyle no stronger than usual, and made to serve as a foundation for fresh mounds of soil. If this did not show confidence in phenyle, nothing I can say or do will emphasise the point. Those plants succeeded as well as any second crop Cucumbers ever did with me, and kept bearing freely as long as it paid to expend fire heat and labour upon late crops generally.

Kainit may be a remedy for eelworm, but the only time it was tried at my expense the remedy proved worse than the disease. The young man in charge of the house was a little too zealous, and did not wait for full instructions. He wished afterwards that he had. As far as I could ascertain, about 8 ozs. were applied to every yard run of ridge, or enough to just whiten it; but it played sad havoc with the Cucumber plants. As far as Cucumbers are concerned, we will dispense with kainit, if you please. Kainit applied too strongly injures the tender stems of young Tomato and Cucumber plants, and poisons the soil. It is safe enough in moderate quantities well mixed with the top spit of a Tomato border, but should be kept out of the small mounds of soil that Cucumbers ought to be planted in. We swear by soot, but even this had better be applied "little and often," and in the form of clear soot water, than very strongly in the compost.

On referring to my Journal I find that something more ought to be said concerning the manurial properties of phenyle. If the marked improvement repeatedly observed in the colour of the foliage and the progress of the plants very shortly after applying phenyle is not due to the manurial properties contained in it, to what else can it be attributed? I am inclined to think there is something in it which "Halogen" has not discovered. Let him try again. If the results of his investigations had appeared two years ago and I had acted in accordance therewith it is certain that I should not have had such healthy plants generally and profitable crops of Cucumbers and Tomatoes as I have been able to produce; in fact, I should have been misled by laboratory teaching. Applied as we apply it, Little's soluble phenyle is worth all it costs us as a manure alone.—W. IGGULDEN.

[How now, "Halogen" and Mr. Dyke? When one person kills his plants with Little's soluble phenyle and another cures them of eelworm by its use; when one says it contains practically no manurial properties, while another avers that it produces "marked improvement" in the foliage, we repeat there is something wrong somewhere. Has it been used, in the case of fatalities, when the soil was too dry? Is it like somebody's tea, "always good alike" when distributed by vendors?]

CYPRIPEDIUM F. S. ROBERTS.

At the last meeting of the Royal Horticultural Society, held in the Drill Hall, on January 11th, Messrs. H. Low & Co., Clapton, showed, amongst other Orchids, a *Cypripedium*, named F. S. Roberts. Of this we give an illustration (fig. 12). It is a hybrid, but the exhibitors omitted to give the parentage. The flower is very handsome, and quite distinct from all others. The ground colour throughout the dorsal sepals, petals, and the pouch is a dull white, over which are strewn numberless spots of claret crimson. The pouch has a patch of this colour on the front. The Orchid Committee of the Society recommended an award of merit.

MASDEVALLIA ARMINI.

It cannot be said that this plant is common, despite the fact that it was introduced so far back as 1882. Such being the case, we are not surprised that "Young Orchid Grower" has not seen it. No doubt the accompanying note and woodcut (fig. 13, page 83) will give him all the information he requires. Messrs. J. Veitch & Sons, Ltd., in their monograph of the *Masdevallias*, give the following description and note:—"Leaves oblong-lanceolate, $1\frac{1}{2}$ inch long, narrowed below into a somewhat slender petiole as long as the blade. Scapes slender, longer than the leaves, one-flowered. Perianth tube short, whitish; free portion of sepals crimson-purple, the dorsal one sub-orbicular, concave; the lateral two broadly oval oblong, nearly flat, and contracted to filiform, yellowish tails 1-2 inches long. Petals linear-oblong, toothed at the apex, white; lip oblong, reflexed at the tip, where there is a blackish purple warty blotch. First discovered on the Eastern Cordillera of New Granada, in the Pamplona district, more than thirty years ago, by Schlim, but dedicated by the late Professor Reichenbach to his friend Hermann Wagener, by latinising the Christian name. It appears to have been first introduced into European gardens by Messrs. Sander & Co. of St. Albans in 1882."

ODONTOGLOSSUM PULCHELLUM.

Few Orchids are more refined and beautiful than this aptly named species, the erect spikes of pure white blossoms always eliciting the warmest praise from those seeing it for the first time. It has bright green oblong pseudo-bulbs and narrow leaves, those at the base enclosing the flower spikes. It is not a difficult plant to grow, and if imported in good condition may be established with very little trouble. Masses of the plant, perhaps a foot or so across, are occasionally to be had from the sale rooms, and these have a fine effect when in flower owing to the number of spikes they carry.

If much shrivelled they should be laid out in a warm moist house for a time, but I have frequently potted them as received with the best results. In no case must much compost be allowed; even when the plants are well established they dislike a lot of material about them. For small plants fill the pots to within an inch of the rim with crocks, and over this lay a little rough sphagnum moss, then place the plant in position and fill up with equal parts of peat and moss, with plenty of rough crocks and charcoal intermixed. Take care that the plants are well firmed, and that the material is good, for *O. pulchellum* has a great dislike for disturbance.

Trim the compost off neatly, and place the plants without avoidable delay in their growing quarters. This species likes a long season of growth; indeed it may be said to be always more or less active, and as soon as the flower spike appears the young shoots also begin to move. As this is in the dead of winter, it is important that all available light reaches the plants, and no filth of any kind must be allowed on the glass to obstruct this. Plenty of moisture will be needed as the days lengthen, and must be continued right up to the time the pseudo-bulbs are finished.

Then if ever there should be a slight diminution before the strain of flowering comes upon the plant, but nothing like a drying system must be practised. Many of the cool section of *Odontoglossums* are best repotted in autumn, but I have had the best results with this plant by doing it immediately after flowering before the young shoots commence rooting. All the year round a cool moist atmosphere is required, and this necessitates heavy shading from May onwards.

Light in winter, shade in summer, and always a moist atmosphere, these are the cardinal points in its culture. *O. pulchellum* was introduced to this country by the late Mr. Bateman, who received it from its discoverer, Mr. G. Ure Skinner, in 1840. It is a native of Guatemala.

ANGRÆCUM SESQUIPEDALE.

This remarkable species of *Angræcum* is now flowering, the pure white blossoms, with the marvellously elongated spur, having a distinct appearance from those of any other plant, and once seen can never be forgotten. The plant itself is of stiff, erect habit, handsome when well furnished with leaves, but too often having a lanky, ungainly look owing to the loss of the lower tiers. This is not, however, confined to cultivated plants, but is even more frequent among imported specimens, owing to the fact that in their native habitat they grow nearly or quite exposed to the full glare of a tropical sun. Collectors of the plant say that these ragged, untidy looking plants are those that flower most freely, this doubtless being the result of the thorough baking they get.

But under cultivation it is a blemish, for it is quite possible to grow the plants and make them flower freely without the loss of a single leaf. Light they undoubtedly require, but we must temper the sunlight for them a little by shading lightly during the heat of the day. It is a noteworthy fact that *A. sesquipedale* will thrive in a

FIG. 12.—CYPRIPEDIUM F. S. ROBERTS.

very much drier atmosphere than most of the distichous leaved kinds, and if there are dryish places in a house where these are not doing well their places may be taken by the *Angræcums*, with advantage to one, if not to both.

It delights in a high temperature, and often steadily refuses to start a root or leaf in a house kept cooler than it needs. Where *Dendrobiums* of the deciduous class, and the usual run of *Aërides* and *Phalænopsis* thrive, there will usually be heat enough for the *Angræcum* while growing. During the winter the temperature must not go below 60°, except on the very coldest nights. With regard to its resting and growing seasons, these are not very sharply defined, and in this it is best to let the plants take their own course. Moisture at the root is essential; less, of course, during winter, but at no time should the roots be absolutely dry.

Sphagnum moss, clean and freshly picked, is by far the best rooting medium when the plants are to be grown in pots or baskets. Plenty of charcoal and ballast may be mixed with it, and abundant drainage provided, as it is important that air reaches the roots and the water passes quickly away. When the plants are left standing long in one position the roots generally leave their pot or basket and cling to whatever is near, such as neighbouring plants, the staging, or even in the case of strong ones, the soil underneath the latter. This shows the need of as large receptacles as may be convenient. *A. sesquipedale* has long been known to science, but did not flower in this

country until 1857, with the Rev. Mr. Ellis, who first imported it alive two years before.—H. R. R.

A FLORIFEROUS CALANTHE.

I SEND you a photo of a curious growth of a *Calanthe Veitchi*. The old bulb is 7 inches long, and it had two growths from the bottom. One of them is 10 inches in length, the first spike 4 feet, with forty-four flowers; second spike 2 feet 6 inches, with thirteen flowers. The second bulb is 6 inches in length, first spike 3 feet, with twenty-four flowers; the second 12 inches, with seven flowers. Then, in addition, there are three small pseudo-bulbs from the very top of the old bulb, one 3 inches long with flower spikes 12 inches, bearing six flowers. The other two are pseudo-bulbs of 2½ inches, with flower spikes containing three and four flowers, so that there are five new growths with 101 from the old bulb. I do not know if you will consider this anything out of the way. I should hardly have expected the small bulbs to flower.—R. DYMOND.

[The novelty consists in the small pseudo-bulbs, issuing from the top of the older and larger, flowering. It is not uncommon for them to be produced, and they are usually taken off and grown for flowering the following year. It is rare for them to flower during the year of production.]

A USEFUL ORCHID STAND.

MOST Orchid growers who have to deal with plants placed over a close wooden stage, upon which has been scattered a layer of shingle, cinders, coke broken small, or similar material, know what it is to have to deal with a troublesome fungus, which forms in the decaying wood and runs into the Orchid pot. I invert flower pots, and on each one a pot containing an Orchid is placed. The other day I turned up some of these, and was horrified to find the fungus had entirely covered the insides of the inverted pots with a cobwebby substance, and had sent snow-white threads through the holes in the base of each pot, the inverted one, and that in which the Orchid was growing, and in several instances had passed up amongst the Orchid roots.

While considering what had better be done to stop the progress of the fungus amongst the Orchid roots, and prevent it in future from attacking the plants at all, there came by post from Mr. Wm. Murray, Wylam-on-Tyne, a series of stands, made of stout wire, exactly in the form of a flower pot. They answer the same purpose as the inverted pot. No fungus can lay hold of this stand; they have a much better appearance than the flower pots, and I could but exclaim, Here is the very thing that is needed to prevent the fungus reaching the Orchid roots, giving us, at the same time, a much neater stand for the plants! The old saying is exemplified: "Necessity is the mother of invention." If Mr. Murray had not had any fungus to deal with, he never would have thought of this useful little stand.—J. DOUGLAS.

EQUAL PRIZES.

JUDGING from the remarks of "Sadoc" (page 597 last volume), this would appear to be an unpopular method of awarding prizes even in close contests, but like Mr. Beckett (page 17) I am of opinion that there are occasional instances where the awarding of equal—not necessarily first prizes, for it is an easier matter sometimes to decide on the first than the remaining cards—is the fairest means of determining when the merits of two competing exhibits are so closely identical.

It is undoubtedly a delicate point to argue, and especially so when the Editor in his footnote gives his casting vote against such a course of action generally. The opinions, even of the Editor and "Sadoc," are in conflict to some extent, for while the latter admits an instance when an "equal" would be justified, the Editor's footnote points out where the determining factor may be found. He also asks, "Were equal prizes ever awarded in the cast of the 'premier' bloom in a Chrysanthemum show?" Yes. I was competing myself at a provincial show in which a certificate and prize in cash was offered for the best bloom in the show, and although the task would seem to have been an easy one, the prize was divided between two blooms, but only one could, of course, claim the certificate. If it had been the work of inexperienced judges one might have made allowance, but this was not so. I have never heard of a similar case, and evidently the Editor is quite a stranger to such unsatisfactory judgment.

It would be, I should say, a most unusual experience to find two groups so close in point of merit, that seven experts were necessary to criticise, and then not to find one spare point. I believe that two judges, well agreed, would find an easier solution to the difficulty than so many. I well remember a case where two Chrysanthemum specialists were engaged in judging the cut bloom section of a good show in the West of England. One had a marked partiality for the Japanese, the other incurred. Here there were a N.C. certificate to be given the best bloom in the show, and after scrutinising closely, they each chose a bloom according to his own fancy, and, unfortunately, neither would give way, each claiming to have the better. In the end other judges were consulted, and neither of the chosen blooms was selected for the coveted honour, but another, and that, too, far removed from being the best, was substituted, and,

needless to say, considerable and severe comment was passed over the undeserved but distinguished victor.

Where the most difficult problems to be decided in the matter of judging is found, according to my experience, is at shows where two men are expected to undertake everything—fruit, vegetables, plants, specimens and groups, florists' and other flowers, bouquets and vases, honey—in fact, everything that is found in the schedule of many local shows. Very few gardeners can claim to be experts in every branch, and they cannot be expected to give unqualified satisfaction to every competitor. I saw two stands of show Dahlias staged last summer at a local show by two rival growers, and to which the judges awarded equal first prizes. This gave satisfaction apparently to everyone except the two exhibitors referred to. Their blooms, taken individually, were so perfect a counterpart one of the other, that it was impossible—except to the growers themselves—to find a determining point making one superior to the other.

No doubt, as "Sadoc" puts it, the awarding of equal prizes makes an easy way out of a difficulty for the judges. It may not be true of the York Show, but mistakes in judging are sometimes attributable to the want of proper time in which to carry out the work; and no matter how qualified judges may be, they cannot concentrate their thoughts and decisions when hampered with visitors, admitted they may be at the advertised hour, but before the judging is finished. Mistakes made under these conditions cannot be wilful, but are the outcome of laxity on the part of the management of the shows. Mr. Harding affords convincing proof of the fairness of giving equal prizes in his contribution (page 66). I am quite prepared to admit that it is only on rare occasions that the necessity for awarding equal prizes occurs, but when there is an instance, such as that quoted by Mr. Harding, justice is done by placing them on equal terms. No exhibitor could feel dissatisfied with such a decision when the merits of their exhibits were so closely identical.—W. S., *Wilts*.

[Our able correspondent does not say to which of the "equal best" blooms the certificate was awarded, and why. If a silver cup had been offered in Mr. Harding's class it would presumably have been withheld because of the high excellence of the produce.]

PEAR NOTES.

IT has never been satisfactorily cleared up why a certain Pear in one locality should be a good melting fruit, and in another only fit for the stewpan; and why in one season a variety should be of excellent quality, and in another only moderately so.

There must be some external cause for this variableness, and surely it is not past finding out. Mr. Dyke's remarks on *Beurré Rance* (page 42) have induced me to pen this note. He says with him it is useless for dessert purposes. I may say it was the same here; we had only a part of a tree of this variety, which had to come away to make room for one of better quality. Some years ago, when living in a moisture-laden atmosphere, the Pear quoted above was delicious, and one of our best winter fruits.

I ask therefore, is it not possible that the hygrometrical conditions of the atmosphere may not have something more to do with the quality of Pears than soil and situation? Both temperature and moisture here are similar to what they are from where Mr. Dyke writes, but the subsoil formation differs. Here we have rather a strong loam resting on a sandstone formation, while I believe Mr. Dyke's loam is of similar texture, but on limestone formation. If I am wrong, perhaps your correspondent will correct me. Be this as it may, the results are the same; therefore I should be glad if some of our friends from the western portions of the kingdom, especially from parts where the atmosphere is heavily charged with moisture, would give their experience of the quality of this Pear; it would help to elucidate my theory or prove its illusiveness.—J. EASTER, *Nostell Priory Gardens*.

DIPLACUS GLUTINOSUS.

THIS old favourite is popularly known as the Tree Mimulus, but though closely allied to the latter is not considered a true Mimulus. Probably no two species of plants could come nearer than these without being quite the same. It is well worthy of being more frequently grown, for though the flowers are not of much use in a cut state, the plants when well grown and covered with the reddish-orange flowers, are admirably suited for the decoration of rooms, and if placed in light positions near windows will remain in a satisfactory state for some considerable time. For this purpose they are with us highly esteemed.

Cuttings of the young growths root easily enough in a Cucumber frame after the plants have done flowering. The pots should be filled with sandy soil, and if a little bottom heat can be provided so much the better. When rooted, pot into 3-inch pots, after which they can be hardened in the greenhouse or a close frame. It is simply a question as to the size of the plants ultimately required in connection with repotting. We find them most suitable in 4 and 5-inch. One stake is placed in the centre of each, according to height, to which the side shoots are loosely tied. After flowering, and when there is no danger of frost, the old plants which are kept are stood outside for a time. They may be planted out during summer in mixed borders, and will sometimes flower fairly well in that position.

The colour of the peculiarly shaped blooms is almost unique, but I find it is greatly influenced by cultivation. If grown sturdily in a good light and well supplied with nourishment the flowers produced will be much deeper in tint than those growing on long weak growths in shaded positions. This plant appears to accommodate itself easily to different soils, but a sandy loam mixed with a small proportion of leaf soil or well-decomposed manure appears to suit its requirements admirably.—J. SHALFORD.

[We think the plant in question is now classed as a true *Mimulus*.]

POINSETTIA PULCHERRIMA.

THIS plant is now very extensively cultivated, and well it deserves to be, as there are few that are more and better adapted for decorative purposes during the winter. The system of culture I have adopted is different from that of many cultivators, but as I have been successful with it for many years, I thought a few remarks on culture would be useful.

The plant is a native of Mexico, having been discovered in that country by Mr. Poinsetti in 1828, and whether different varieties of the species were sent over, or whether the difference in cultivation has the effect of improving the quality of the bracts, I know not, but I certainly have not seen better or more brilliant specimens anywhere than have been produced by the culture here described.

When the flowering period is over the plants are gradually dried off, and the pots laid on their sides underneath the stage in a cool stove, where they remain until the end of March. In that month the young growths of last season are cut down to within three or four eyes from the base of the growth. No water is applied to the roots until the wounds are dried, but the pots are removed to the greenhouse, where they are placed on the stage near the glass, and there they remain, water being applied to the roots when it is required, but no more than is necessary to maintain a healthy growth. They do not require nearly so much water here as they would in the plant stove, where the heat would be 55° or 60° at night.

When the buds have started, and are about half an inch long, the plants must be turned out of the pots and repotted;—and to grow this plant well it requires a rich compost. The following answers admirably: Rich turfy loam five parts, one part decayed stable manure, one part leaf soil, and an 8-inch potful of crushed bones to each barrowload of the compost; a little sand is necessary if the loam is of close texture. Drain the pots well, and place over the broken potsherds some of the fibrous part of the loam from which the clayey particles have been well shaken out; if the finer portion of the compost becomes mixed with the drainage the plants will not retain their leaves to the end of the season. After potting, the plants should be kept near the glass and be fully exposed to sunshine, and the house be freely aired; this will cause the growths to come strong and short-jointed, the leaves to be thick and leathery, and the wood will be of a reddish tint.

Immediately the pots are well filled with roots, which will be by the middle of May, the plants may be repotted in similar compost to the above, and by the middle of June they can be removed to a position out of doors where they are partially shaded from the sun. I have found they do best on the north or west side of a low house where the tops of the plants are exposed to the sun and the lower portion sheltered from its rays. If they are exposed to the direct force of a strong gale of wind many of the leaves are injured. In this position they must not at any time suffer by want of water at the roots, as this would also cause some of the leaves to drop off, and the object of the cultivator is to see that this does not occur, as the loss of the lower or any leaves very much impairs the beauty of the plants.

About the middle of September we remove the plants to a house where there is a night temperature of 50° or 55°, and this ought not to be exceeded until the bracts commence to form, when the night temperature should be 65° until they are fully developed. I ought to mention that as soon as the plants are taken indoors they should be well watered with manure water; every alternate watering may be of guano water. This deepens the green of the stem and leaves and adds brilliancy to the floral bracts.

Propagation is effected by cutting the stem into short lengths and inserting the eyes in the same way as Vine eyes; they thus grow as freely as Vines, requiring very similar treatment. Another method equally simple is this: When the young growths are 3 or 4 inches in length it will often be found that there are more on the plants than ought to be allowed to remain. Let the surplus growths be taken off with heels and be placed in a gentle bottom heat under a bell-glass, where they will, if shaded from the sun, very soon produce roots. If each cutting is potted in sandy loam in a thumb pot the plants will not suffer anything when they are repotted. In three weeks from the time of putting in the cuttings the plants will be ready to be repotted. After being established they may gradually be inured to a cooler atmosphere, and be ultimately placed out of doors and be treated as has been recommended for the established plants.

The Poinsettia does not require very much pot room; the summer-rooted cuttings may be placed in pots 4 inches in diameter, or three can be potted in 6-inch pots. We have some in 6-inch pots from cuttings rooted in June; each pot contains three plants, which stand 15 inches from the surface of the pots, and the floral bracts are as much as 15 inches across.—D. J.

WEATHER IN LONDON.—Mild weather has prevailed in London during the past seven days. With the exception of last Saturday, which was very bright, the days have been dull, but there have been no heavy fogs. Rain has not fallen during this interval, nor is it required. A change to dry, gentle frosts would be appreciated.

— WEATHER IN THE NORTH.—The weather of the past week has again been changeable. In the former part high westerly winds prevailed. After an extremely wet night, Saturday, Sunday, and Monday were good spring-like days, although there was little sunshine. On Sunday morning there was a very slight touch of frost. Tuesday morning was rather dull, but fresh and pleasant.—B. D., S. Perthshire.

— LOST VOTES AT THE RECENT GARDENERS' BENEVOLENT ELECTION.—I am anxious to call the attention of subscribers to the above Institution to the number of votes that were lost through the neglect of several persons in omitting to sign their names to the voting papers, and others failing to pay their subscriptions. No fewer than 1152 votes were lost in this way—a most serious thing for the candidates. It is strange but true that 1035 votes were not signed, and 117 lost through failures in payment. The Orphan Fund election takes place on February 18th. Let me advise those subscribers to be careful and sign their names, and mark their votes plainly in the sheet, to save a repetition of the misfortune to which I draw attention.—ALFRED OUTRAM, F.R.H.S., 7, Moore Park Road, Fulham.

— WOOLTON GARDENERS' IMPROVEMENT SOCIETY.—The annual meeting of the above Society was held under the presidency of the Rev. R. E. Roberts. Mr. H. Corlett had eight microscopes on view, the slides including various plants and insects, the series proving most interesting. A charming collection of Orchids in variety came from Mr. R. Todd, gardener to the President, Holbrook Gaskell, Esq., Woolton Wood. These were highly appreciated. Mr. R. G. Waterman, who has worked so assiduously to make the year's work such a great success, was again unanimously re-elected Hon. Treasurer and Secretary. An effort was made at a social gathering, also by a sale stall at the Sefton Park Show, held by permission of the Liverpool Horticultural Association, by which a donation of £10 17s. 8d. has been forwarded to H. J. Veitch, Esq., Treasurer of the Victorian Era Fund, in connection with the Gardeners' Royal Benevolent Society. A warm tribute was paid to the late Rev. George Beaumont, who had been a Vice-President since the formation of the Society. It was said of him that he did not speak about things he did not know, but when he did speak it was with the confidence of an experienced teacher, and with the quiet certainty of one who had reason to know that his assertions rested on a basis of fact.—R. P. R.

— ROYAL METEOROLOGICAL SOCIETY.—The annual meeting of this Society was held on Wednesday, the 19th inst., at the Institution of Civil Engineers, Mr. E. Mawley, F.R.H.S., President, in the chair. The Secretary read the report of the Council for the year 1897, showing that there had been an increase in the number of Fellows, and that the finances were satisfactory. The President, Mr. Edward Mawley, then gave an address on "Weather Influences on Farm and Garden Crops," in which he pointed out the intimate connection between meteorology, agriculture, and horticulture. He explained the special characteristics of the climate of the British Isles as regards temperature and rainfall. Of all the influences brought to bear on vegetable life by the atmosphere, he considered temperature to be the most powerful and far reaching, and only second to this came rainfall. The leading effects of snow, wind, and sunshine, as well as of prolonged droughts, severe frosts, and persistent rains were also described. He then dealt with the influence of different important weather changes on such farm crops as Wheat, roots, and grass, as well as on fruit trees, vegetables, and flowering plants in the garden. In his concluding remarks he called attention to the great want of experimental farms in conjunction with meteorological stations being established in this and other countries in Europe, for it was only by the examination of meteorological observations, together with weekly records of the extent and character of the growth made by our leading crops, that the close connection existing between weather changes and their influences on such crops could be clearly traced. Mr. F. C. Bayard, L.L.M., was elected President for the year.

— NATIONAL VIOLA SOCIETY.—A Committee meeting of this Society will be held on Thursday, the 27th inst., to arrange schedule of prizes for the forthcoming season. The Hon. Secretary is Mr. R. T. Dougall, 52, Pembroke Road, Walthamstow, Essex.

— DEATH OF AN OLD FLORIST.—Midland and other florists will learn with regret of the death of Mr. J. P. Sharp, aged seventy-nine years, which took place on the 20th inst., at his residence, King's Heath, Birmingham. The deceased was a well-known florist, especially in the cultivation of Carnations, Picotees, Auriculas, and Tulips, around Birmingham; also as an exhibitor of the same some years ago. He was the raiser of such Picotees as the heavy red-edged varieties—Mrs. Sharp, Campanini, and others.

— NEWCASTLE-ON-TYNE FLOWER SHOWS.—We have received a copy of the schedule of the above. The spring show will be held in the Olympia on Wednesday and Thursday, 20th and 21st April, and the summer show in the Recreation Ground, in conjunction with the Northumberland Agricultural Show, on Wednesday, Thursday, and Friday, 13th, 14th, and 15th July, 1898. The Royal Horticultural Society's Council have accepted an invitation to be present, and will send a deputation with full powers to make awards. The attendance at the last joint show, in the year 1893, was enormous, and the financial result was a very successful one. Copies of the schedule may be had from the Secretary, 54, Westgate Road.

— THE ABNORMAL WEATHER ABROAD.—An evening paper says, "As in England, so on the Continent. The infallible 'oldest inhabitant' cannot remember such a mild winter in Germany as the present one. Reports from all parts of the country speak of the spring-like weather now prevailing. In South Thuringia grass is being mown in the meadows, and the storks and starlings have returned from their winter quarters. A list of the flowers in bloom in the same district has just been drawn up by a botanist residing there. It includes twenty kinds of spring flowers, among them being Daisies, Dandelions, Ranunculus, Ladies' Fingers, Strawberries, Wild Pansies, Meadow Grass, Speedwell, Brambles, Raspberries, Violets, and, in the gardens, Christmas Roses."

— THE WEATHER OF 1897.—The wind was in a westerly direction ninety-two days. The total rainfall was 25.16 inches, which fell on 194 days, and is 1.63 inch below the average for the year. The greatest daily fall was 1.28 inch on July 26th. August was the wettest month, with 4.51 inches. Barometer (corrected and reduced): Highest reading, 30.708 inches on November 21st; lowest, 28.575 inches on March 3rd. Thermometers: Highest in the shade, 88° on August 5th; lowest, 19° on December 23rd. Mean of daily maxima, 55.60°; mean of daily minima, 41.19°. Mean temperature of the year, 48.39°. Lowest on the grass, 16° on April 11th and December 23rd; highest in the sun, 145° on June 28th and July 12th. Mean of earth temperature at 3 feet, 48.64°. Total sunshine, 1549 hours. There were seventy-one sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham.*

— THE GARDENERS' ORPHAN FUND.—How strange it is that many gardeners, and especially fathers of young families, cannot be induced to subscribe, if but 5s. annually, to the Orphan Fund. Hundreds do, and thousands do not. In the ballot papers for the ensuing election there are eighteen candidates for election, but of sixteen families only, as in two cases members of the same family are, I consider most improperly, nominated. The rules ought to forbid that certainly. But out of the sixteen cases not one in the descriptions attached mentions, "Father a subscriber to the Fund." This is worse than unfortunate, it is culpable neglect. People who have never shown the least desire to support the Fund in life scruple not to let the subscriptions of other gardeners be used for the maintenance of their children should they become orphans. Surely it is time some conditions as to subscriptions were imposed, as nothing seems to be at present done to enforce amongst a large section of gardeners the principle of self-help. It will be interesting to notice results when the election takes place. Some applications are of a very pathetic nature, others show very little indeed of hardship. Will those cases that strike any unbiassed subscriber as demanding the greatest sympathy be successful, or will those candidates be returned who, apart from merit, have the largest number of friends, either in the country or at court? After all, as is well known, it is in the latter place where elections are won. To make the ballot a reality, every subscriber should fill up his or her ballot papers as they desire, sign them, and return them to the Secretary direct, and if votes were given solely because of the merits of the case, and not because of favour or influence, great good would result.—A GARDENER.

— GARDENING APPOINTMENT.—Mr. John Haynes (for several years a well-known successful gardener at Edgbaston, Birmingham), has been engaged as head gardener to — Lamb, Esq. (an opulent Manchester manufacturer), at Studley Castle. There were no less than eighty applicants for the situation in question.

— A ROSARIAN'S LEGACY TO THE BIBLE SOCIETY.—It was recently announced that under the will of the late Rev. E. N. Pochin the Bible Society will receive a sum of not less than £80,000. As the widow, two sons, and daughter were passed over in the will, the Committee of the Society have, after most careful examination into all the circumstances of the case, and under legal advice, felt it their duty to undertake to relinquish for the benefit of the family half of whatever sum the Society may eventually receive under the will.

— BIRMINGHAM GARDENERS' ASSOCIATION.—On the 24th inst. a special meeting of this Society was convened for the purpose of appointing a new Secretary in the place of Mr. John Hughes, who was mainly responsible for the inauguration of the Society. Mr. Hughes' increasing duties in other channels, and more especially as Secretary of the Birmingham Chrysanthemum Society, rendered it necessary that he should relegate the duties in question to some other member of the Association. Mr. W. B. Latham (the Chairman), Mr. Walter Jones, and Mr. John Child respectively acknowledged the invaluable and gratuitous services which Mr. Hughes had rendered towards the Society. Mr. William Deedman (foreman in the Botanical Gardens, Edgbaston) was elected as the future Secretary.

— "GARDEN NOTES FOR THE COLONIES AND ABROAD."—Such is the title of a trade medium that has been issued by the well known firm of Messrs. James Carter & Co. Apart from the fact that there are not, in the ordinary acceptance of the term, colonies "at home," it is all the same apparent that the publication gives a great amount of compressed information on the nature and capacities of many countries as producers of useful products of the soil. It is the second edition that is before us, accompanied by a notification that all the available copies of the first edition were acquired by one of the colonial governments for distribution. This was a good beginning, and it is not at all unlikely that the demand will grow for the first work of the kind we have seen, and which seems to cover all the civilised as well as the recently "tapped" uncivilised portions of the earth. The work in its way has been done well, and there is plenty of it for a shilling.

— ATTRACTION OF FLOWERS FOR INSECTS.—Professor Plateau states in "Nature" that, in seeking for pollen or nectar, insects are guided only to a subsidiary extent by the sense of sight. They continue to visit scented flowers after the coloured parts have been almost entirely removed. When flowers of the same species vary in colour, they exhibit neither preference nor antipathy for one colour over another. Inconspicuous flowers hidden among foliage attract large numbers of insects. Artificial flowers made of paper or calico, even when brightly coloured and closely resembling real flowers, are not visited by insects; but they are when made of green leaves which have a vegetable scent. If flowers which have little or no nectar, and which are therefore habitually neglected by insects, are smeared with honey, insects are attracted in large numbers. On the other hand, if the nectary is removed from flowers habitually visited, their visits cease at once. From all these facts and other facts the conclusion is drawn that the guiding sense to insects in visiting flowers must be chiefly the sense of smell.

— ORIENTAL AND AMERICAN LILIES IN SCOTLAND.—Having been desirous for some time past of ascertaining how Lilies fare in the North-East of Scotland I have learned on inquiry that the following are most successfully cultivated in the county of Aberdeenshire—viz., *Lilium auratum platyphyllum*, generally supposed to be the most enduring of the section to which it belongs, it also produces the largest flowers; *Lilium auratum rubro-vittatum*, the red-banded variety, which is not so strong growing as nor yet so prolific of its flowers as the other auratums; *Lilium pardalinum*, the Californian "Panther Lily," which grows in Aberdeenshire exceedingly strong; *Lilium Browni* and *Lilium Kramerii*, which, though very beautiful, are somewhat sparing of their blooms, while the latter is not very easily cultivated, though originally brought by its introducer, Mr. Kramer, from a high altitude among the mountains of Japan; *Lilium Martagon album* and its more valuable sport or variation, *album superbum*, which grows more vigorously and produces larger flowers. *Lilium candidum*, *tigrinum splendens*, and *Fortuni*; *L. davuricum*, an early blooming Lily from Siberia; *Lilium calcedonicum*, *Lilium Szovitzianum*, a noble variety of the Martagonian sub-genus from the regions of Mount Caucasus, are also largely and successfully cultivated in North-Eastern Scotland.—D. R. W.

— **VEITCH MEMORIAL TRUST.**—At a meeting of the Trustees, held on January 19th, Dr. Maxwell Masters in the chair, it was unanimously resolved that medals for objects to be hereafter determined should be allotted for the present year at exhibitions to be held at Bristol, Leicester, and Cardiff respectively. A sum of £20 was voted to the Trustees of the Lindley Library towards the preparation of the catalogue now in progress. Medals were also allotted to M. Marliac in recognition of his success as a hybridiser, to M. André of Paris, and to M. le Comte de Kerchove of Ghent, President of the Royal Agricultural and Botanical Society of Ghent, for their respective services to horticulture.

— **APPLE COURT PENDÛ PLAT.**—A correspondent writes (on 20th inst.): "I was all round Birmingham yesterday, and only met with one lot of English Apples, and that was Court Pendû Plat." We have for many years found this a reliable and serviceable late dessert Apple in use from January to April. Dr. Hogg, in his "Fruit Manual," states the name *Court pendû* signifies *suspended short*, "the stalk being so short that it sits, as it were, upon the branch." That is precisely its character. It became known as Garnons Apple in Herefordshire through having long been grown without a name in the gardens of the Cotterell family of that city. In Nottinghamshire it is called Woolaton Pippin, from the residence of Lord Middleton. Its popular name is the *Wise Apple*, through the blossoms unfolding so late as to usually escape injury from spring frosts.

— **A DREAM OF THE FUTURE.**—In this beautifully written and very possible outlook (page 52) it is startling to find this sentence, "I seemed to miss the cornfields, but soon perceived they were things of the past." To my mind it is the one great danger impending over this country—the extent to which already we are dependant on other lands for our corn. How many weeks' supply does this country ever contain? and how would the corn ships get here in case of a war? At any instant a war might break out with Russia, then one of our principal sources of supply is at once cut off; if America were also to withhold it we should be brought to our knees at once; if not, famine prices would raise a clamour which would make us seek peace at any price. The storage of corn, and the increase of acres under cultivation, will have to receive attention unless the nation is prepared for the gravest calamities. We are the only country in Christendom—nay, in the world—that is content to accept of such a perilous position.—A. C.

— **READING GARDENERS' ASSOCIATION.**—Under the auspices of this successful Horticultural Association a tea and smoking concert was held in the Abbey Hall on Monday, 17th inst. Nearly 100 members sat down to tea, which was presided over by the President, Mr. C. B. Stevens. The tables were decorated with plants from the gardens of East Thorpe (Mr. Woolford, gardener). After justice had been done to an excellent repast, the Chairman proceeded to propose the usual loyal toast, and in so doing said that they, as an Association, were greatly honoured, for on the occasion of their annual outing, which took place in July last to Windsor, they had not only the pleasure of looking through the gardens and grounds at Windsor and Frogmore, but by her Majesty's gracious permission they were allowed to inspect also the "private portion" of the gardens at the latter place. They were greatly indebted to Mr. Owen Thomas, the Queen's gardener, for having spoken on their behalf.

— **INDISCREET NATURE.**—The mildness of the weather is evidenced in some of the consignments to Covent Garden Market, where there were to be seen last Saturday numerous clumps of Primroses and bunches of Snowdrops. Violets—nearly all foreign—are, it may be added, a drug in the market. The wholesale price is about four bunches a penny for lots of ten dozen, and as these are subdivided by street and shop vendors some idea can be obtained of the profits. Judging from the innumerable letters we have received, Nature is everywhere being deceived. Crocuses are in bloom in Kent, and white Roses in the gardens of the Langland Bay Hotel, near Swansea. In some parts of Lincolnshire Primroses have been flowering for the last week or two, and even Roses may occasionally be seen blooming in the open garden. Pansies are also much to the front, reports from Welling, Kent, and Bournemouth showing them to be quite common. In the latter place the *Doronicum*, which usually comes out in May, is already in bloom. Tales of venturesome butterflies and indiscreet birds, who have brought their young progenies into the world several months too soon, continue to reach us. One blackbird signalled Christmas Day by laying an egg in a nest secreted in the Ivy of the Aylsham Workhouse. A correspondent who sends us the last interesting item also states that he has just seen a nest containing three young sparrows in the Ivy of the workhouse at Swaffham, Norfolk.—("Daily Mail.")

— **PROFITS IN BANANA CULTURE.**—It is remarkable how many people there are among the lovers of fruits and flowers who, in the language of Scripture, "have eyes but see not, and ears but hear not." The cultivation of the Banana is the case in point. Banana fruit is now among the commonest of our fruit in market, and it is within the reach of even the poorest, and yet a quarter of a century ago they were scarcely known, to any great extent, out of the land in which they grew. At the present time, says a transatlantic paper, shipments are made from Jamaica to different parts of the world amounting to 3,000,000 of dollars annually. There is no reason why such an extended culture could not have been started a hundred years ago. It must be said, however, that the cheap and rapid means of transportation, by means of the steamship companies, has undoubtedly had to do with the progress in this industry.

— **THE HESSLE GARDENERS' SOCIETY.**—A large number of members attended a meeting of the above Society, held on Tuesday, January 18th, to hear Mr. Peake, Superintendent of the Hull parks and gardens, read a paper on "Hardy Shrubs and Plants in Towns." Those who had heard Mr. Peake on previous occasions expected a treat, and they were not disappointed. The essayist described the most suitable varieties of evergreen, deciduous and climbing shrubs, classifying them for the different localities according to their powers of endurance and the conditions of the soil. Herbaceous plants and several varieties of florists' flowers then followed, and these were served in a similar manner to the shrubs. Mr. Barker showed well-grown plants of *Cypripedium* *Leeanum*, *C. Pitcherianum*, and *C. purpuratum*, arranged on the table with *Pandanus Veitchi* and Ferns. A vote of thanks to the essayist and Chairman (Mr. J. P. Leadbetter, Tranby Croft Gardens) terminated the meeting.—G. W. G.

— **TECHNICAL EDUCATION IN WARWICKSHIRE.**—The last of a course of lectures on horticulture, arranged by the local Technical Education Committee, was given in the Board School on Monday evening last. Mr. H. Dunkin, F.R.H.S., has been the lecturer, and the interesting and instructive manner in which he deals with each subject is productive of the greatest possible attention from his audience. An average attendance of upwards of forty is a proof that lecturer and subject are popular in the district. The subjects dealt with have been: "Soils and Manures;" "How and When to Plant Fruit Trees;" "Insect Pests and the Mode of Destruction;" "Grafting and Budding;" "Pruning;" and "Vegetable Culture." Pruning was illustrated in a very practical way by several large Currant and Gooseberry bushes (just such as are seen in almost every cottage garden), branches of fruit trees being pruned and each step carefully explained. Mr. Dunkin evidently takes great pains in the preparation of his lectures, the information he imparts being useful and practical; and as he speaks from actual experience it is not surprising they are attended with success.—("Leamington Gazette.")

— **ARTIFICIAL MANURES.**—I could scarcely believe Mr. Dyke was serious in writing that he dressed his Tomato borders, in a house I presume, with 2 lbs. 12 ozs. of artificial manure per square yard. His assertion that after all this is a trifling bulk when it is mixed with 900 lbs. of soil, only shows how terribly poor must that soil have been to need such a wanton bulk of dressing. The analogy drawn from the application of manures with potting soil is not applicable, as in a border, especially broken up 12 inches deep, Tomato plants put out, say, 15 inches apart, would have for root run six times the room and soil they would have in a 10-inch pot. Pot culture of any plant is essentially artificial, and artificial treatment alone will produce success. Planting Tomato plants out in an ordinary soil border can hardly be so described. But 2 lbs. 12 ozs. of these manures per yard means fully 82 lbs. per rod, and just about 6 tons per acre. It is only needful to go so far to show the very costly as well as wasteful form of dressing referred to. Now, one assumption derived from what is told us, and a very natural one also, seeing that the plant and fruit product does not seem to have been one whit the better than Tomato growers ordinarily obtain on ordinary soil, is that the manures mentioned—basic slag and kainit—are either practically worthless, or were not in the form applied utilised by the crop at all. This is not the first time we have heard of soil being poisoned by excessive manure dressings, for here is furnished what ought to be plant food enough at one dressing to serve for a dozen at least. I have seen plenty of fine crops of Tomatoes obtained from very ordinary soil, assisted during the summer with soot dressings or waterings, and occasional very light sprinklings of chemical manures, bearing no comparison to the waste of the applications cited by Mr. Dyke.—A. D.

VEGETABLES FOR HOME AND EXHIBITION.

(Continued from page 30.)

CABBAGE.

No apologies are needed for placing this amongst the most important vegetables. Early spring Cabbage is welcomed as being the forerunner of other favoured vegetables, and the market grower produces nothing more profitable when his facilities are such that he is able to place spring Cabbage on the market a few days before his neighbours. The plant, broadly speaking, may be said to thrive anywhere and under any ordinary conditions, though it gives the best returns in fertile soil and under systematic methods of culture. All members of the Brassica family are gross feeders, and the Cabbage is no exception. Good farmyard manure is the food it revels in, and the plant will appreciate all it obtains in the way of suitable nourishment.

In the cultivation of this crop one important point should never be lost sight of—namely, Succession. The first sowing should take place about the middle of February, and artificial heat being then necessary, it is best to choose an early variety and sow the seeds thinly in boxes, placing this in a propagating pit or heated frame. When large enough, the plants must be pricked out in light soil in a frame, and as the season advances be gradually hardened until they can be removed to their permanent quarters. The soil should be prepared beforehand by deeply digging and incorporating good manure, then lift the young plants with balls of earth attached, so that there shall be no check in the growth, and all other conditions being favourable, a bed of useful summer Cabbage will be the result.

Sowing number two is for the autumn supply, and should be made early in April, though in this case little protection is needed when pricking from the seed boxes. If no ground is actually vacant, the plants may be placed as other crops come off, though it is always well to have a reserve plot, as leaving them too long before transplanting is not an incentive to their well-doing. Cabbage from the second sowing may be obtained tender and fresh late into the autumn, and it is questionable whether the vegetable is ever more appreciated if we except those from the earliest spring cutting.

The third sowing is to provide spring Cabbage, and is allowed to be the most important of the trio. Locality has all to do with the actual time of sowing, as in warm southern districts it would be a mistake to sow so early as in the colder north; therefore no hard and fast rule can be enforced, and sowings may be made from the second or third week in July to the middle of the following month. Good strong plants are wanted to withstand the rigour of winter, but rank overgrown plants are the first to succumb to a severe spell of frost. It is a common and good plan to make two sowings during the period stated—the first of a Colewort, and the second of a good hearting variety of Cabbage. No transplanting is necessary in this case, as the plants, raised thinly, may be removed from the seed bed to their permanent quarters, those not required being left to fill up vacancies in the spring.

Quarters that have carried summer crops are well suited for Cabbage, the soil being rich with manure and fairly firm, as if too loose and friable there is a danger of that rankness of autumnal growth against which we should endeavour to guard. The distance apart varies according to the variety, though from a foot to 18 inches is ample. Planting should take place if possible during showery weather, and failing that water must be given as the work proceeds. The plants should be watched in severe weather, as frequently flocks of half-starved linnets will find them, and very soon nothing remains but a mass of riddled stalks. When the plants commence growing in the spring keep the surface soil stirred with the hoe and draw a little round the stems. At this period a stimulant applied as a top-dressing works wonders, and the difference in the growth of the plants after the dressing is very apparent.

The field of variety among Cabbage is a wide one, and for size and form there are sorts to suit all tastes. Small conical heads are much appreciated at some dinner tables, and where such is the case Little Pixie and others of the same type are admirable for the purpose. Ellam's Early is still a prime favourite as a spring Cabbage, and Mein's No. 1 and Wheeler's Imperial must be mentioned amongst the best. For size and weight Enfield Market and Defiance are two varieties hard to beat and extremely popular, and for sowing in the spring for summer and autumn cutting Early York is very good. It is needless to make more than a passing reference to the usefulness of Cabbage sprouts, which form after the heads have been cut. Frequently these are relied on for succession instead of planting for summer and autumn use, though the latter course is recommended.

In regard to exhibition, I still stand to my argument that the best heads of Cabbage for the dinner table are the best for show, and this theory would, of course, debar those monsters of cultivation that one frequently sees obtaining first prizes over the heads of smaller Cabbages, though superior in quality. Very large Cabbages are rank and strong, and, as a rule, have a huge tough stalk penetrating the heart, which deteriorates their value as an article of food. Medium-sized heads, firm,

well filled with hearts good and sound, are the kind one would naturally choose to eat, and if quality is to be the main thing looked for by judges, then it is such Cabbage that should receive the first consideration on the exhibition table.—GROWER AND JUDGE.

FAIR DEVON.

(Continued from page 28.)

THE Strawberries relied upon are few. Sir Joseph Paxton is the first favourite, and is found far more satisfactory than any others, though President and Princess Alice Maud are included in many plantations. Royal Sovereign has found its way into some of the holdings, but it is not much more than under trial; and it is strange that more varieties have not been tried, especially in the early sections, for necessarily it is mainly upon the early crops that the producers depend. But they find Sir J. Paxton so uniformly reliable that they are naturally reluctant to make a change without any substantial reason. With regard to the distances for planting preference is given to $2\frac{1}{2}$ feet between the plants in the rows, thus allowing more space for the gatherers and for general cultivation. It is considered that the plantations continue profitable for four or five years, and some point to beds that have been in bearing for ten or twelve years, but the latter are exceptional. In my experience, and I believe that is in accord with the majority who have a large extent of land under Strawberries, the plants are very little use after the third year, and some even advocate treating the plants as biennials, though this does not allow much margin for losses occasioned by bad seasons.

One rather interesting fact deserves notice in connection with this part of the subject—namely, October planting is both advocated and practised by some with the object of preventing the plants bearing the first year, as it is found that the second crop is then so much larger and better in every way. One very observant man who has had considerable experience was very emphatic on this point, though it differs materially from the opinion of many growers in other counties. It is usually reckoned that the finest fruits are secured from the one-year plants, and this is undoubtedly what does take place, but whether the crop in an ordinary way pays for gathering is another matter. In favourable seasons with very strong plants early rooted and early planted, the first season's crop will give a good return, but otherwise I am inclined to think there is something in our Devon friend's practice. It has a bearing, too, upon spring planting, which might be expected to exercise a check in the direction of non-cropping in the first season, and for my own part I would sooner plant Strawberries in spring than late in the year, especially if the soil and weather conditions are unsuitable in autumn.

Besides the Strawberries, Cherries of the small black or Mazzard type are extensively grown, the trees presenting a beautiful feature in the landscape when covered with flowers, as they are in most seasons. The average crops of fruits are also very heavy, but are disposed of at low prices, Plymouth providing a convenient market for these, though it is said to be less advantageous for Strawberries, which secure better prices in London, or even more northern cities, notwithstanding the long distance by rail, with the cost and risk of carriage. Taking it altogether, however, this fruit district is an extremely interesting portion of Devonshire, and some of the owners there must regard it very favourably, seeing what a difference it has made in the rental of the land.

A traveller in Devonshire, particularly if he journey by road, cannot fail to have his attention arrested by the peculiar, usually very picturesque or occasionally prim, hedges and wall-like field or road boundaries. The "stone fences" of this county are as characteristic a feature as the "dry walls" of Derbyshire and neighbouring counties, only they have much more in their favour from an artistic point of view. It would not be practicable to construct such boundaries except in districts where stone is very abundant and easily procured; but the soil in many parts of Devon abounds in stone or rock of all sizes, even the arable land is similarly stocked, and the local saying, "Miss a stone and meet a guinea," is supposed to represent equal probabilities. The ploughing or digging of some of the land would puzzle cultivators who have to deal with the mellow stoneless soil of the Thames valley for instance, and the mere handling of a true Devonshire shovel would be a novel experience to most gardeners in northern counties. The instrument is, however, well suited to the character of the soil, the long handle slightly curved downwards towards the base, the large flat heart-shaped blade being turned up at a slight angle, and it is astonishing to see the amount of work a vigorous labourer can get through in soil that could not be dug with ordinary straight-blade spades, or even with forks.

Returning to the "stone fences," which deserve a few words of description, it must be said that they are expensive to form, but

compensation is found in the fact that they require scarcely any further attention, and last for an indefinite time. They vary both in height and width, but the average might be taken at about 5 feet in height, 6 to 9 feet wide at the base, and 2½ or 3 feet wide at the top. A cone of earth is formed proportionate to the size of "fence" required, and this is then faced with stone, and the workmen who have become skilful by long practice at this construct as even and regular faces as the best bricklayers could do. Upon the soil at the apex of the cone young seedling Beech are planted, and are usually protected from cattle for the first few years by a wire stretched along each side projecting from the wall at the top. The cost of such work necessarily differs somewhat in proportion to the size of the "fence," but the usual rate is 3s. to 4s. per yard run, or at least four times the cost of a Thorn hedge, though the cost of keeping and trimming the latter is constant, and in the other case it is practically nil. In a district exposed to strong gales such "fences" afford valuable

Apart from all other considerations, that is the most likely means of leading to constant disappointment and failure. It is unnecessary, too, for there are several firms of nurserymen advertising in the Journal columns who make a speciality of British Ferns, and who send out well-established plants in pots at moderate prices. Unquestionably there is a great degree of interest in growing Ferns found by oneself, but there are few of the species which grow on the stone fences or walls that can be transplanted successfully.—VIATOR.

(To be continued.)

A "CURIOUS" METHOD OF PRODUCING EARLY POTATOES.

As you have thought the "curious" Potato sent you by Mr. W. Brown worth figuring, I have thought you might consider the following worth printing. It may interest some of your readers. In the early

FIG. 13.—MASDEVALLIA ARMINI. (See page 77.)

protection for stock, and very rarely need repair. When the Beech is well established it makes a dense and beautiful hedge, even in winter, as the yellow-brown leaves are retained so long.

Though not an intentional or practical use these "fences" serve another purpose, which can perhaps only be duly appreciated by the lovers of some of our most graceful British plants, the Ferns, that find in the crevices and crannies between the stones a congenial home. It is possible to travel for miles along some of the roads where the fences are older, and to find scarcely one square yard unoccupied by colonies of exquisite Ferns, in some instances diminutive gems, and in others vigorous examples of their respective species. It is a Fern hunter's paradise, but in places Vandals have been busy, and have stripped the "fences" of their natural ornaments. It is doubtful, however, if the charms of our native Ferns are generally appreciated as they deserve to be, for there are many amongst them that will rival in elegance of frondage the most costly and delicate exotics. A proportion do not lend themselves readily to cultivation it is true, but a number can with ordinary care be satisfactorily grown on rockeries and in cool houses. It must not be supposed for a moment that I advocate a wholesale tearing up of wild Ferns by amateur cultivators.

forties, when I was employed in what was then considered one of the foremost early forcing places in Middlesex, and where early fruits and vegetables were cultivated with a measure of success I have never seen excelled, Potatoes were required as early as they could possibly be produced, and this was accomplished in January.

The previous season the necessary number of the largest tubers that could be collected from both farm and garden were thinly stored in the coolest place available. They were, after a certain date, looked regularly over at short intervals, and every attempt at growth checked by rubbing off every growth as soon as it appeared.

Early in autumn the tubers were placed in deep boxes in layers, not too thickly, alternately with finely sifted layers of dry loam. The position chosen for this was a shed in which were two furnaces, and was therefore moderately warm. Very soon a young tuber was forced out from every eye of the old tuber. The crop was examined at intervals, and as soon as they had attained sufficient size the young tubers were removed from the parent, and sent to table in the ordinary way. The crop never failed. The secret of success lay in preventing the exhaustion of the large tubers by being allowed to grow in the ordinary way.—D. THOMSON.

[We well remember this method being practised late in the "forties," and many dishes of new Potatoes from the size of unshelled to shelled Walnuts obtained.]

THE N.C.S. AND THE ROYAL AQUARIUM—A REVIEW.

ALTHOUGH the correspondence which has taken place upon this subject has been somewhat lengthy, no true lover of the Chrysanthemum can fail to recognise that the importance of the question which has been raised fully justifies the space accorded to it, and especially should the members of the N.C.S. be grateful to the *Journal of Horticulture* for so generous a concession of its columns to a matter so vital to their interests.

As a looker-on is said to "see most of the game," will you allow me, as one who has been beside the fray, to state the conclusions to which the correspondence has carried me? The first thing which is apparent is the absolutely one-sided character of the correspondence; indeed, so overwhelming is the predominance of opinion expressed on the one side, and so limited and really insubstantial the pleas put forward by the other, that it is no exaggeration to say that the facts are not seriously in dispute. What, then, are the essential facts? They appear to be these.

For over twenty years the National Society, having under its special charge perhaps the most generally popular and widely cultivated flower in existence, has carried on its exhibitions in alliance with the Royal Aquarium. The N.C.S. has the largest number of members of any special horticultural society, and in those twenty years it has accumulated a reserve fund of £100 (£5 a year), an annual increase for such purpose that has been far exceeded by a local suburban horticultural society.

The holding of the Society's exhibitions at the Royal Aquarium has, even from the first, proved very objectionable to a large and influential class of admirers of the Chrysanthemum, and is probably responsible for the conspicuous absence from the Society's managing body of any substantial number of amateurs of position. Some persons may be attracted by the *menu* provided by the Royal Aquarium, but certainly, to put it mildly, as many, and those at least as influential, are repelled. As a place of exhibition, apart from merely moral or æsthetic considerations, the Royal Aquarium has never provided those essentials of fair competitive exhibition—space and light sufficient to permit of a due estimate by the judges being made of the relative values of the exhibits staged—the wonder being that exhibitors having reputations to sustain should be found willing to jeopardise them by competing under such conditions. How many are deterred we can never know. Nor have there been adequate facilities for the inspection of the exhibits by the public.

But bad as have been these conditions in the past, they have become by degrees immeasurably worse as the patience of the Committee of the N.C.S. has become more and more plainly inexhaustible; and as its Secretary has more and more emphatically and publicly announced his opinion that the Society cannot possibly exist but by the kind consideration of the Royal Aquarium, until in November last, to the unbiassed spectator, there was presented not a thing which by any standard could be considered a show worthy of a National Society, but so gross a travesty of what such a show should be—and this in face of all that an experienced and energetic Secretary could do with the materials at his disposal—that the patience of most members of the Society, if not of its Committee, was exhausted, and the correspondence in your columns followed.

The Royal Aquarium authorities appear to have decided to try the experiment of reaching the "irreducible minimum" which the N.C.S. would put up with, and to weight the cord of the Society's patience almost to the breaking point. The question is whether they have not broken it.

It is scarcely necessary to comment in detail on the arguments *pro* and *con* which have turned on the financial question. Briefly, the Secretary contends that although show after show, resulting in brilliant financial success, has been held in provincial towns, the great metropolis of London cannot be relied on, even with a National Society, to do what Edinburgh has done, and what Birmingham has done, with merely local effort and *prestige*. Figures, purely fanciful, and without any stated authority, have been quoted in opposition to those appearing in his own Society's published balance-sheet. He pleads for the Royal Aquarium that, for recompense for its generosity towards the N.C.S., it has to depend on "the uncertain takings at the gates," and almost in the same breath points out that so great is the attractive power of the Chrysanthemum, that it "attracts to the Aquarium yearly thousands of persons" to see it in its "fullest glory."

Scarcely consistent, perhaps, but can any reasonable being seriously doubt that, given a covered building to keep the rain out, in a fairly accessible situation, this immense metropolis will ever furnish its "thousands," good weather or indifferent, to support a really typical and national show of so universal a favourite as the Chrysanthemum? Does anyone think that a serious financial disaster is really possible?

The "last ditch" of those who uphold the present condition of affairs is that there is absolutely no alternative place to the Royal Aquarium. Truly there may be no place quite so central. But there, surely, all advantage ceases. No place can be more unsuitable in every other respect; in fact, if we are to believe that the provision made by the Royal Aquarium authorities at the late November Show is to represent that to be accorded in the future, then it seems that the question of departure is already settled, and the only point remaining is which of the alternative sites—Earl's Court, the Agricultural Hall, or, possibly, some other place—shall be selected for the holding of the show, or shows, of the National Chrysanthemum Society, freed from the taint of its music hall associations, but supported by the numberless lovers of its special flower.

But, then, we are told by the gentleman himself—the Secretary of the N.C.S.—that if this should be done he will instantly resign his position as officer of the Society. Mr. Richard Dean has done good, very good, service for the N.C.S. So had, before him, the late Mr. W. Holmes. When the latter died there were many who thought that his loss would prove irreparable. It was left to Mr. R. Dean to prove anew the truth of the adage that "there are as good fish in the sea as ever came out of it," and he must not be hurt if it be suggested that the example which he himself supplied has not exhausted the application of the adage. Well, is "the tail to wag the dog," or "the dog the tail?" That is the real question. If the National Chrysanthemum Society, represented by its elected Committee, should arrive at the conclusion that the good of the Society requires the removal of its exhibitions from the Royal Aquarium, then its will must prevail, and must not suffer influence by any such considerations as that suggested.

There are some, as the correspondence shows, who evidently think that the Secretary holds the Committee in the hollow of his hand—and the Royal Aquarium the Secretary. This probably is not the case, but, anyway, the members of the N.C.S. have it in their power to compel obedience to their behests, and the responsibility rests with them.

It has been suggested by some that the Society's exhibitions might be more strictly confined to the Chrysanthemum, and that financial considerations might require that two shows at most should be held by the Society; while others propose that one great metropolitan show, and a provincial show in alliance with local societies in affiliation (as in the case of the N.R.S.), would best serve to render financial disaster impossible, and to erect the Society upon a really sound foundation of *Nationality*. There is much, it seems to me, in this last suggestion.—SPECTATOR.

[Beyond this review, which is the more weighty because of the evident desire of the author of it to be strictly impartial—while recognising "essential facts"—we are unable to afford space for other communications on the subject this week. At the same time we do not absolutely shut the door. We have letters in hand and one in type, though it is not for these the door is left ajar; but rather because if even yet an impartial and unbiassed defender of the alliance of the National Chrysanthemum Society and Royal Aquarium Company should desire to set forth clearly the advantages to the N.C.S. of such alliance, we should not like to deny him the opportunity. As the matter now stands the alliance is admitted and deplored in more than twenty letters which have appeared, because the several writers have been given to understand by one of its defenders that the Aquarium is the dominating partner. The initial note which called forth such a remarkable expression of feeling and opinion, and which led to the reasonable ventilation of a public grievance, appeared in our issue of November 5th, and the discussion has been continued in the nine consecutive issues to the present date. We yield to no one in the sincerity of our desire for the prosperity of the National Chrysanthemum Society, and the stronger and more widely representative it can be made by a far-seeing Committee the greater our satisfaction will be. It has often been necessary to amputate a limb to save a life.]

AN INTERNATIONAL CHRYSANTHEMUM AUDIT IN FRANCE.

To the majority of English cultivators and admirers of Chrysanthemums, the result of the above election will hardly commend itself as being of value. The position occupied by Madame Carnot will commend itself to all lovers of the flower. If there is such a thing as a "best" Chrysanthemum, Madame Carnot surely has a strong claim to the honour; but when we come to Le Colosse Grenoblois, which occupied the second place in the audit, it is rarely seen in England, much less admired. Mrs. C. Harman Payne is regarded as being much too coarse to find favour, and is being fast ousted from whatever high position it once held. Madame Ed. Roger, the new green flowering variety, is placed fourth on the list, actually in front of Vivian Morel, Australian Gold, Phœbus, and Chenon de Leché. At the best, Madame E. Roger can only claim its tint of green to captivate on-lookers, and I am at a loss to

know to what section it belongs. It can only be love for the peculiar that places *L'Isere* before Charles Davis. Fancy, too, Philadelphia occupying a much higher position than Robert Owen, itself one of the best of Japanese incurved varieties. I regard an audit of Chrysanthemums, Roses, Potatoes, Apples, or aught else, in an educational point of view, as being a means of instruction in the selection of varieties. The audit under consideration, however, I regard as being purely a sentimental one.—SADOC.

CHRYSANTHEMUM JOSEPH CHAMBERLAIN.

THIS variety was missed from my list of new Japanese, which I much regret. As an exhibition bloom it should do good service. A seedling from Edwin Molyneux, it possesses much of the brilliant colour of that variety, yet lacks a trifle of its brightness. From the raiser, Mr. H. Weeks, Thrumpton, Derby, I a short time since received blooms gathered from plants growing out of doors, and certainly they were very fine examples, showing what a really deserving Japanese variety it is. Typical blooms are large enough for any purpose, the florets being long, flat, and of medium width. The colour, bright glowing crimson, is a welcome addition, intensified as it is by the golden reverse of each floret.

CHRYSANTHEMUM WHITE MRS. FILKINS.

This is one of the many novelties sent out by Mr. H. Cannell during the last twenty years. Certainly it is not the least important of the additions made to the Chrysanthemum list. In size, form, and character the new comer resembles its parent, but is pure white. For wreaths and bouquets, as well as for the decoration of the dwelling house in vases, a great future lies before this Chrysanthemum.—E. MOLYNEUX.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the General Committee of this Society was held on Monday evening last at Anderton's Hotel, Fleet Street, Mr. T. W. Sanders presiding. Much of the business was purely of a formal nature, such as correspondence, notifications of special prizes, and a consideration of the proposed new rules to be submitted to the annual meeting, the chief item of which is the suggested appointment of a Finance Committee. The Classification Committee will hold a meeting on Monday next, to take into consideration various Chrysanthemums of doubtful classification. A rough financial statement was submitted, and also an estimate of the value of the prizes to be offered for competition at the Society's shows during the ensuing year. The annual meeting will be held on 28th February. Several new members were elected.

THE BEST VARIETIES.

THE question may well be asked "Who is to decide?" in reference to the best sixty, fifty, or any particular number of varieties. For my part I cannot perceive any particular gain obtainable from lists which include the oldest and latest introductions so confusedly mixed. What the average amateur grower—and, indeed, the professional, too—is more directly concerned about is the best of the modern or latest novelties. The best twelve, twenty-four, or thirty-six of the season 1897-98 given by the leading experts would impart more valuable information than the tabulating of old and new ones in the order of their individual merits.

Mr. Wells' list includes some that have lost ground, and with many growers are entirely discarded, notably Mrs. C. H. Payne, Madame M. Ricord, Mdle. Thérèse Rey, and International. However, this is but a brief list of objections out of so long a list, and it cannot be disputed that the selection of sorts given is a good one. It could not be expected that Mr. Wells' list would be a counterpart of Mr. Godfrey's; tastes vary, and so do varieties of Chrysanthemums under different growers' treatment. It is strange that *Etoile de Lyon*, which is so universally accounted coarse, should still commend itself to notice and be shown so frequently as it is; and Mrs. C. H. Payne is even worse, size is its only quality, and it is doubtful whether its white sport has come to stay.

The Editor's announcement of a promised list of the best, determined by so large a number of growers, will now be anticipated, and opportunities will be afforded of comparing the select stock and allow of additions to be made where it is considered necessary. Mr. Molyneux's selections have been read with the usual interest, and his advice proved a help to many. A small selection for market work, early, midseason, or late, would be useful to a large section of your readers, so would one for private growers who do not require so limited a selection, because a different purpose is required of them.—W. S., Wilts.

HUMEA ELEGANS.—It is not too much to say that this beautiful plant cannot be surpassed for general effectiveness in the flower garden during the summer months, for whether as a back row to a ribbon border, as a single specimen to sink into the lawn, or to form "dot" plants in the beds, its graceful orange-red drooping plumes have a charming effect, especially when planted near a rivulet or fountain. The culture of the *Humea* is very simple, and I have found that a cool treatment during autumn and winter for those plants intended for planting out is much the best. The seed is sown in the early part of July in pans of well-prepared light soil, placed on a shelf in a warm house, and covered with a piece of glass. When the seedlings make their appearance the glass is removed, and the receptacles placed in a cooler house near the roof glass. When the rough leaf is reached we prick them off into thumb pots, keeping shaded from the bright sun for a few days, afterwards removing them to a cold frame. They are potted as required in a compost of equal parts loam, leaf soil, and well decayed manure, with sand added. On the approach of severe weather the plants should be removed to a suitable house for the winter, the temperature of which is kept at about 45° to 50°.—H. T. M.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ANNUAL GENERAL MEETING.

AS is customary, Simpson's Hotel, in the Strand, was the meeting place for the officers and friends of this admirable Charity, at the annual general meeting on Thursday last. From a point of view of numbers the gathering was a comparatively small one, but everyone present was a loyal supporter, so that the business was despatched very expeditiously. Prior to the ordinary there was a special general meeting to appoint Trustees, in the place of the late Dr. Robert Hogg, and of Mr. John Lee, who has resigned. The gentlemen selected were the Hon. Walter Rothschild and Bruno Schröder, Esq., both of whom are well-known financiers, and whose appointments cannot be other than a matter for congratulation to the members of the Society. These gentlemen having been unanimously elected, the ordinary meeting was entered upon, under the chairmanship of Mr. Harry J. Veitch. Amongst those present were Dr. Maxwell T. Masters, and Messrs. Arthur W. Sutton, Thos. Manning, A. Outram, W. Cobb, Jas. H. Veitch, J. Fraser, W. Roupell, W. Denning, J. Willard, J. Hudson, A. F. Barron, and W. White (Worcester Auxiliary), with Mr. G. J. Ingram, the popular Secretary. The first proceeding was the reading of the report and balance-sheet for the past year, and readers will find on perusing these how satisfactory is the status of the Society, and how carefully and judiciously it is managed.

REPORT OF THE COMMITTEE FOR 1897.

It affords the Committee considerable satisfaction to submit their annual report for the year 1897, together with an audited statement of accounts, and in doing so they are thankful to be able to record the continued prosperity of the Institution, and its increased benefit to those old and needy people in whose behalf it was founded.

With great pleasure the Committee have to report that the fifty-ninth anniversary festival dinner in aid of the funds held in May last was most successful, and they desire to express their gratitude to the Right Hon. Lord Rothschild for so kindly occupying the chair on that occasion, and for his able advocacy of the claims of the Charity, which met with so liberal a response. They would also gratefully acknowledge their indebtedness to those gentlemen who so kindly served as Stewards, to those who sent flowers and fruit, and to other friends who in any way assisted in making the festival a complete success.

During the past year nineteen pensioners have died, seven of them leaving widows, of whom five, whose cases on being carefully investigated and found to be in every way satisfactory, have been placed on the pension list at £16 a year, in succession to their late husbands, in accordance with Rule III., 13. The Committee have now the pleasure to announce that they have decided to add nineteen additional pensioners to the number now on the funds, ten of whom, having been accepted under Rule III., 5, they recommend the subscribers to place on the pension list without the trouble and expense of an election; the remaining nine will be elected by votes from the approved list of candidates in the usual way. This addition will make the total number of pensioners 168, the largest number of beneficiaries receiving permanent aid since the foundation of the Institution. And yet there will be thirty-five unsuccessful candidates who will perforce have to wait for that assistance which they so much need. The Committee heartily wish it were possible for them to render aid to a larger number, but with financial responsibilities to those now on the funds, which are impossible to accurately calculate, they do not feel in a position to recommend a further increase in the annual expenditure than that entailed by the addition of the number already stated.

In the past year there have been in aid of the Charity held an amateur operatic performance at St. George's Hall, kindly organised by Mr. H. Morgan Veitch; a flower and fruit stall at the Richmond Horticultural Exhibition, kindly arranged by Mrs. Algernon Chancellor; garden fêtes at Reigate and other places, concerts at Altrincham, and various other functions in different parts of the country, to the promoters of which, one and all, the Committee tender their very hearty and sincere thanks. They would also gratefully recognise the self-denying labours of the Hon. Secretaries of the several auxiliaries, which are still attended with marked success, and are the means of creating a widened interest in the good work of the Institution.

It will be remembered that the Committee in their last report announced their intention to send to each unsuccessful candidate at the 1897 election the sum of £5 on June 21st, in honour of the Diamond Jubilee. This they are happy to say was done, and the grateful letters of acknowledgement received from the recipients showed how greatly appreciated were the welcome and, in many cases, timely gifts. The Committee likewise announced that they had inaugurated a fund to commemorate the long and beneficent reign of our beloved Queen—the Patroness of the Charity. This fund, by her Majesty's gracious permission, they proposed to call the "Victorian Era Fund." They are now gratified beyond measure to state that the appeal issued in its behalf was most generously responded to, the sum of £4075 being received, which amount has been invested in the names of the Trustees in Great Western Railway 3 per cent. guaranteed consolidated stock, and the interest derived therefrom will be annually divided *pro rata* amongst those unsuccessful candidates who formerly were subscribers to the Institution, in order to render them some temporary assistance whilst awaiting election, but no candidate may receive more than £10 in any one year.

The Committee would like to mention the names of all those who have so liberally and kindly contributed to this special object; but whilst

gratefully thanking all who did so, they hope it may not seem invidious if they particularise a few generous and munificent donations which greatly helped to secure the substantial amount raised:—His Grace the Duke of Westminster, President; Lord Rothschild and Messrs. N. M. Rothschild & Sons; the Baron Schröder, Vice-President; Harry J. Veitch, Esq., Treasurer; N. N. Sherwood, Esq., Trustee; C. Czarnikow, Esq., Vice-President; Arthur W. Sutton, Esq., member of Committee; George Monro, Esq., member of Committee.

The Committee are happy to acknowledge the following legacies which they have received:—£457 5s. 11d. from the late Mr. J. W. Thomson, formerly gardener to his Majesty King George III., for the purpose of applying the interest for the special benefit of a widow or widows, and £100 from the late Colonel Thos. Page, formerly a life member of the Institution. They also thankfully acknowledge the receipt, just before the close of the year, of special donations to the general funds of £50 from the Royal Scottish Horticultural Society, and £26 5s. from the Royal Caledonian Horticultural Society.

In common with other Charities, the Committee have to deplore the removal by death of several friends and supporters, amongst whom may be mentioned the late Dr. Hogg, a Vice-President and Trustee, who for many years took a warm and practical interest in the Institution, and the late Mr. Richard Chrimes, who for upwards of thirty years had been a liberal subscriber to its funds; the late Lord Hindlip and J. Travers Smith,

We have audited the accounts and certify the same to be correct, and are pleased to state that we have found the books well and accurately kept.

We have also satisfied ourselves that the securities of the invested funds are in the hands of the Bankers.

(Signed) Jan. 18th, 1898.

THOMAS MANNING.
THOMAS SWIFT.
JESSE WILLARD.

In rising to move the adoption of the report and balance as read the Chairman made some trenchant remarks on the features therein, and considered that the details were so explicit as to render detailed references superfluous. He observed that the past year must be considered as the best in the annals of the Institution, both as regards work done and income received. Touching allusion was made to the late Dr. Hogg, and a tribute was paid to his energy in the past, as well as to the services of Mr. John Lee. The Chairman spoke briefly about the Victorian Era Fund, and was of the opinion that the amount subscribed was excellent, more especially when the many calls upon the purses of donors in the Jubilee year were borne in mind. Mr. Gardner seconded the motion, which was carried without a dissentient voice.

The election of officers for the ensuing year was then proceeded with, and, needless to say, Mr. H. J. Veitch was asked to continue in the position he so worthily holds, while Mr. G. J. Ingram was re-elected Secretary, and Auditors and Arbitrators also stand unchanged. Mr. W. Morgan proposed that Messrs. W. Denning, J. Douglas, N. Sherwood, J. H. Veitch, and G. Wythes be re-elected members of the Committee, and that Messrs. E. Ranger Johnson and W. Gleeson be elected in the place of Messrs. R. A. Milligan Hogg and T. Glen, who retire.

Mr. W. Denning moved, and Mr. H. E. Tillman seconded, that Messrs. John Battersby, John Berry, Daniel Brockham, George Daniels, William Davidson, Thomas Ffoulkes, John Mitchinson, John Perkins, John Rolfe, and Silas Warr, whose cases have been investigated and come within the terms of Rule III., 5, be placed upon the pension list without election from January 1st, 1898. This was carried, and having appointed Messrs. A. Outram, T. Manning, and E. J. Monro scrutineers of the ballot the company dispersed until the declaration of the result of the poll.

DECLARATION OF THE POLL.

The result of the polling of votes for the election of new pensioners upon the funds of the Institution was declared at 4.50 P.M. The names of the nine successful candidates for election were read out by Mr. A. Outram, and were as follows:—Henry Ellis, 4249; Thomas Bundy, 3900; Robert Begbie, 3878; James Baker, 3868; Wm. Wood, 3790; David Cornell, 3663; George Hewitt, 3651; Edwin Thomas, 3550; and Lydia

both of whom had been annual subscribers for many years. They have also to record that in consequence of advancing age Mr. John Lee has felt compelled to relinquish his position as a Trustee of the Institution. From its commencement Mr. John Lee has been one of its warmest friends, and whilst accepting his resignation with the deepest regret, they know that as long as he may be spared he will continue to take a special interest in its welfare. It is a source of much gratification for the Committee to notify that the Hon. Walter Rothschild and Bruno Schröder, Esq., have consented to fill the vacant Trusteeships, and they desire to express their sincere thanks to those gentlemen for so kindly giving their services in this way to the Institution.

In concluding their report the Committee have to make the welcome announcement that the fifty-ninth anniversary festival dinner in aid of the funds will be celebrated on Wednesday, June 8th next, at the Hotel Metropole, when his Grace the Duke of Portland (Vice-President) has kindly undertaken to preside, and from a long experience they are encouraged to hope that all those friends who have the well-being of the Charity at heart will again do in this sixtieth year of its history, all in their power to insure the success of the anniversary. And whilst rejoicing in the solid prosperity of the Charity, they still earnestly invite the kind co-operation of its present supporters in procuring new subscribers, so that its work may be not only fully maintained, but enlarged, and the ever-increasing number of applicants helped and benefited.

Rose, 3534. Mrs. Elizabeth McCulloch, who receives 3031 votes, being the second widow on the list, was elected to receive the benefit of the interest accruing from Mr. Thomson's legacy. The interest of this legacy is scarcely sufficient to support a beneficiary, and it was decided by the Committee that the deficiency should be made good from the general funds. Mrs. Elizabeth McCulloch will in future be known as the Thomson pensioner.

It was announced that the poll that day had been the heaviest on record, no fewer than 97,951 votes having been registered. It is a matter of much regret, however, that the spoiled votes should have aggregated to so heavy a total as 1152. Of these 1035 were brought about by the neglect of the voters to sign the ballot papers in the prescribed way. The remaining 117 votes were nullified by reason of the fact that the voters were in arrears with their subscriptions, as according to the laws of the Society votes coming from such quarters cannot be recognised.

THE ANNUAL FRIENDLY SUPPER.

This was held at 6 P.M. in an adjoining room, a goodly number of members and friends sitting down to a well-served repast. A. W. Sutton, V.M.H., Esq., of Reading, occupied the chair. The musical arrangements were, by the kindness of the Chairman, placed in the hands of the Red Band. A lengthy list of toasts, interspersed with vocal and instrumental music, had been drawn up, and after the physical man had been well attended to this was proceeded with. The services of Mr. Mel. B. Spurr of the Egyptian Hall had been secured by the Chairman, and his songs and musical sketches were received with vociferous applause and general pleasure.

After the customary loyal toast had been honoured, the toast of the evening, "Continued Prosperity to our Institution and the Victorian Era Fund," was given by the Chairman. Mr. Sutton said that his association with the Society was a comparatively short one, and dated only from last year, but he was greatly struck with the efficiency of its organisation. He then briefly reviewed the most salient points in the history of the Society. It was started in 1838, and in 1851 Queen Victoria became its patroness and the Prince Consort its patron. In 1864 the Prince of Wales took the place of his deceased father as patron. In 1851 the total

receipts were £748, and a sum of £512 was awarded to thirty-five pensioners. Now the pensioners were 168 in number, and a sum of £3000 was disbursed annually amongst them. Since the Institution was inaugurated £71,000 had been distributed to deserving persons. The year lately closed had been the most prosperous the Society had ever had, for while the total receipts in 1896 were £4739, in 1897 they were £8575, or nearly double. This was of course due to the special appeal for the Victorian Era Fund. Mr. Sutton paid a great tribute of praise to the energy and business ability of the esteemed Secretary, Mr. G. J. Ingram, and mentioned a case where, owing to foresight and promptitude, Mr. Ingram had obtained from the legacy left to charity by Mr. Thomas Gibbs £250 for the Society. In conclusion he expressed his regret that the Institution could not help even more than it had done and was still doing. He coupled with the toast the name of Mr. H. J. Veitch, who, in responding, said that he, in common with all the officers of the Society, was actuated by a desire to do his best. He then proceeded to supplement the facts, showing how well they had progressed, which had been given by the Chairman and by others, dealing especially with the last ten years. The funded property of the Society ten years ago was £21,000, but at that time the interest in Consols was reduced, and a larger amount had to be invested to make up for this. Now the vested funds amounted to £29,000. Ten years ago they had 126 pensioners, now there were 168, more pensioners having put on the books during the last two years than in any other three. Ten years ago there were no auxiliary societies; now there were several, including a very healthy one at Worcester. He was sorry to say, however, that practical gardeners did not support the Society as they ought to do. Mr. Veitch mentioned the shadow that had passed over them in the loss of the two Trustees, Dr. Hogg and Mr. John Lee. Speaking of the Victorian Era Fund he said it was destined for the relief of unsuccessful candidates who had been subscribers. He had made a calculation with regard to the amount of money to be paid to those who benefited under this fund, and it would range from £10 downwards, according to the respective lengths of their subscriptions. They required £5000 to complete the scheme, and although they had not been able to collect all this the fund was still open, and he hoped yet to see the full £5000 in hand.

Mr. Bunyard proposed "The Committee," coupling this with the name of Mr. Owen Thomas. He was pleased when Mr. Sutton joined the Committee, as he felt sure that the Society would profit by his business ability and experience. Mr. Owen Thomas, in replying, spoke to his regret at the absence of Mr. G. Munro. He thought that the Society could well congratulate itself on its satisfactory position. It was to Mr. H. J. Veitch that they were indebted for the establishment of the Victorian Era Fund. In the absence of the Rev. W. Wilks the toast of "Our Country Friends and Supporters" was given by Mr. H. B. May, Mr. J. H. White, of the Gloucester Auxiliary, replying. Although they had nearly been jubileed to death at Gloucester, he said, their contributions amounted to 250 guineas during the twenty-seven months their branch had been started, and he hoped to be able to send further substantial sums in the near future. He thought that every county should have its auxiliary society. Mr. N. N. Sherwood gave "The Chairman," who suitably responded.

A most enjoyable evening was spent, and this was largely due to some capital songs by Messrs. Fred Bevan, J. H. White, concertina solos by Mr. Fred Bevan, and a cornet solo by Mr. Edwin G. Munro, all of which were much appreciated and heartily applauded. The arrangements altogether reflected great credit upon those who organised and executed them.

BRIEF NOTES ON ALPINE FLOWERS.

(Continued from page 18.)

POLYGALA CHAMÆBUXUS.

THE Box-leaved Milkwort, as it is popularly termed, is one of the dwarf evergreen shrubs which are alike useful in or out of bloom. It is neat in habit, and its little flowers are very pleasing with their Pea-like blooms. *Polygala Chamæbuxus* is by no means a new plant, its introduction dating back to more than 230 years ago. By the seventeenth century botanists the plant was named *Chamæbuxus*, from Greek words signifying "low-growing Box." On the adoption of the name *Polygala* the former generic name was retained as the specific one.

The Box-leaved Milkwort is partial to a peaty soil with a fair amount of sand intermixed. It may also be grown in soil of a heavier texture, and in this will grow taller and more robust looking. In light peaty soil its height is from about 6 to 9 inches, but in that of a stronger character it may grow 1 foot high. It was introduced from the Austrian and Swiss Alps, and it has been observed that on the granite formations, and particularly in the Southern Tyrol, the variety with purple flowers occurs. The ordinary species has small Pea-shaped looking flowers, white and pale yellow at first, the latter colour afterwards deepening to dark yellow, and on some parts to brown. The leaves of the plant are fairly well described by the popular name of "Box-like" Milkwort, and much resemble those of the dwarf Box used for edging walks. It comes into bloom in April (or in late seasons May), and flowers for several months.

P. Chamæbuxus is not a difficult plant to propagate, the process being effected by taking off slips or cuttings with a "heel" of the old wood attached, and inserting these in small pots filled with light soil and surfaced with sand. These pots are then carefully watered and kept close and shaded for some time. Plants which are of some size may be divided in the end of August or in September. One cannot recommend too highly this neat little Milkwort.

LEIOPHYLLUM BUXIFOLIUM.

This little plant has as many aliases as a professional rogue. These have given, and still give, a good deal of trouble and annoyance to gardeners and others. It has been named *L. Lyoni*, *L. prostratum*, *L. serpyllifolium*, and *L. thymifolium*, as well as *Ledum buxifolium*, *L. serpyllifolium*, and *L. thymifolium*. I received it under the name of *Ledum Lyoni*, but the authority of the Kew "Index" is ample warrant for the use of the name of *Leiophyllum buxifolium*, which is here adopted. To judge by appearance *L. serpyllifolium* or *L. thymifolium* (which latter name Maund says applies to the small-leaved form) would be more in accordance with the leaf features of this pretty Sand Myrtle.

It comes from Carolina and the Pine barrens of New Jersey, and was introduced in 1736. Its full height is about 1 foot, but it does not often grow so high, and from 4 to 9 inches is more commonly its stature. It belongs to the natural order of *Ericaceæ*, and is of compact, bushy, and evergreen habit. The small, pinkish-white flowers open in May or June, and grow in corymbs at the ends of the branches. The leaves are small,

FIG. 14.—OLEARIA STELLULATA.

and in autumn some assume a reddish colour. A cool situation in sandy peat is that recommended for *L. buxifolium*, and care must be taken that it never becomes too dry or the leaves may drop. It is increased by careful division or by layers.

OLEARIA HAASTI.

It is not every one of the Daisy Bushes which can be safely planted in the rock garden without some winter protection. Haast's Daisy Bush is, however, the hardiest of all the *Olearias*, and is pleasing in winter or spring with its glossy evergreen leaves, or in autumn with its heads of white Daisy-like blooms. It comes into flower in August, the flower heads being arranged in cymes. The leaves, which are about an inch long, are elliptical in form, and are glossy green above and white beneath.

O. Haasti grows from 2 to 4 feet or more high. It is a native of New Zealand, and seems to thrive well in almost any soil. I think it inferior in beauty of flower to *O. stellulata* (fig. 14), but for the decoration of the rock garden in winter it has some advantages by reason of the greater brightness of its foliage. It can easily be kept within bounds by pruning or cutting back. The recognised method of propagation is by means of half-ripened shoots put into sandy soil, under a bell-glass, and shaded. I have, however, successfully struck slips or cuttings, taken off with a heel, and placed in pots in a greenhouse.—ALPINUS.

(To be continued.)

THE TROPICAL SUMMERS OF 1896-97: THEIR EFFECTS ON THE FRUIT TREES AND FRUIT CROPS.

IN reviewing the many-sided effects of the tropical summers of 1896-97, the facts range themselves as favourable and unfavourable. The tropical heat, combined with drying winds, and that general absence of rain during the spring months of the period under notice, dried the soil to an unusual extent; and although in 1896 abundant autumnal rains fell, in 1897 the months of September and October were the driest known for years. The effect of the heavy rains of the autumn of 1896 was felt in the activity of the sap and the adhesion of foliage on fruit trees rather later than usual, and consequently the trees did not get that rest which is as necessary for the vegetable world as for the animal creation; and we agree with Mr. R. D. Blackmore that the general failure of fruit crops in the spring of 1897 was largely due to that cause.

There was a want of power in the trees themselves to lay up the necessary nutriment, and ability to perfect embryo fruit buds, at a critical period, [and as reported in the gardening papers, many cases of imperfect blossoms were noted in fruits, and doubtless many more facts would have been discovered had they been suspected and looked for. To outward appearance the blossoms were perfect, the corollas being bold, as usual; but in many individuals either stamens or pistils were wanting, and no doubt also the upper or fruit-nourishing roots suffered from the want of surface moisture, and thus were prevented from doing their work—while lower anchor roots struck deeper and deeper to gain moisture and sustenance for the development of the tree, making it less fertile, and adding gross wood to all garden trees, and thus trees were found to require root-pruning more than usual to restore that relative balance of fruit and wood-producing power which a well managed fruit tree should exhibit.

In orchards (especially among young trees) the lack of fruit was a distinct benefit, as the trees were better able to form vigorous growth before starting to crop, and thus lay a foundation for full development and after success: as if a young orchard tree commences to crop in its earlier stages, its after-growth is checked for years, and in the future such checked trees produce pecks where bushels of fruit should be garnered. In the dry autumn of 1897 matters were different, and the glorious and gorgeous colours of the foliage on Cherries, Peaches, and Nectarines, and the fine russet-brown of the Apple foliage, and the golden Plum leaves, leads us to infer that Nature's work has been well and truly done, and with a fair spring a good all-round crop may be anticipated in 1898.

Although from a nurseryman's point of view the shorter and stouter growth fruit trees made in 1896-97 meant some loss and extra expense in staking standard trees, still the growers cannot fail to be great gainers in having the wood of fruit trees well ripened, hardened, and consolidated for future benefit, as heavy frosts tell much less severely on such perfected trees. If this is felt in the south, how much more must it benefit planters who live in the midland and northern counties! The pretty fruit shown by Mr. Day from Galloway, and the grand Pears from Mr. Divers, Belvoir Castle Gardens, sent to the Royal Horticultural Society, bear out this fully.

The fruit crop of the Jubilee year, 1897, will be noted in our minds for its remarkably high colour and development more than for great size. Many examples submitted to us have been beautiful beyond all former years: for example, crimson Blenheim Orange Apples, Warner's King, and other green Apples with scarlet flushes on the sunny side. Doyenné du Comice and other Pears had lovely red cheeks, while many Russets lost their character and come out with golden skins, only broken here and there with russet. Many of the less hardy Apples, as Lord Suffield, Ribston Pippin, King of Pippins, and Glou Morceau, Bergamot Esperen, Gansel's Bergamot, and other Pears, have been so handsome and good that planters have called for them freely, forgetting that they are not to be relied upon (as a rule) for freedom from canker or quality. Their extra good appearance and flavour point a moral, and doubtless we ought to place these and similar good but variable Apples on walls or in warmer places. Apples of the type of American Mother, Melon, Scarlet Nonpareil, Allen's Everlasting, Duke of Devonshire, Sturmer Pippin, with those that do not always ripen well, such as Calville Blanc, Boston Russet, Calville Rouge, Reinette du Canada, Dutch Mignonne with Beurré Diel, Bergamot Esperen, Olivier des Serres, Beurré Rance, Beurré Baltet, President Osmonville, Easter Beurré, and Zéphirin Grégoire Pears, would not be out of place on many walls which are well situated, and now devoted to a doubtful crop of Peaches or Nectarines, especially those old walls, unpointed and full of nail-holes, one often sees in ancestral gardens, where choice Pears and Apples would flourish and give good results.

The extended use of large and handsome Apples for decoration should lead growers to place Peasgood's Nonesuch, Buckingham, Belle de Pontoise, The Queen, King of Tomkin's County, Twenty Ounce, Gascoigne's Seedling, and others on walls for this purpose.

One special feature of the 1897 fruit crops was the general success of the British raised varieties, such as Nonpareil, Northern Greening, Wyken Pippin, Blenheim Orange, Devonshire Quarrenden, Yellow Ingestre, Stirling Castle, Wellington, Ecklinville, Kerry Pippin, Keswick Codlin, Winter Queening, Nanny, Hornead Pearmain, Lane's Prince Albert among Apples; and Hessel (Hessle), Althorp Crassane, Hacon's Incomparable, Bishop's Thumb, Pitmaston Duchess, Crawford, Aston Town, Eyewood, and Knight's Monarch among Pears, causing a demand to arise for trees of many old and superseded kinds, which for market purposes are yet valuable. The general crops on the Codlin and early Apples and

Pears need only to be noted to state the fact that such kinds have time to recover themselves after the fruit is gathered, and so prove regularly fertile.

Exceptional prices have been made of some fruits. In our district Devonshire Quarrenden, Yellow Ingestre, and Ribston Pippin Apples sold well (one grower selling 100 bushels of the latter as gathered at 14s. 6d. per bushel), while Cox's Orange Pippins made up to 25s. per bushel retail, and Wellingtons, with a Peach-like colour, made 10s. 6d. wholesale.

As might be expected, the heat and drought has caused all late Pears to ripen months before their usual season, and by the time this is in print many fruit rooms will scarcely have a Pear in them. At present Olivier des Serres and Beurré de Jonghe, with a few Easter Beurré from open trees, are all we possess. But we are inclined to think thorough ripening will allow us to keep Apples as late as usual, though they will certainly not be so large; in short, beauty will compensate for mere size.

Perhaps no outside fruit felt the grand weather of 1896-7 more than Peaches and Nectarines on walls. The trees made that reddish wood so dear to the cultivator's eye, and the crop set well; while the fruit where the trees were copiously watered grew to a fine size, and coloured to perfection, raising the almost lost hopes of many old gardeners to encourage them to persevere in their open-wall cultivation; those who had late Peaches made long prices, as the fruit under glass was forwarded by the heat, and thus made a market for the outdoor crop. Peaches and Nectarines are yearly more in demand. We attribute the failure of the Plum crop to the causes already named, which by their surface-rooting nature would naturally be affected more than deeper-rooting fruits.

We cannot refrain from again cautioning gardeners from relying on a few varieties for an annual crop; and the best for quality should be planted in various positions to insure a return, and also to lengthen the season of each kind. Market growers naturally go in for the sorts favoured by the public, but we are inclined to think many less known but reliable croppers should be introduced. Strawberries, Raspberries, and bush fruits generally cropped where good deep cultivation was practised.

In conclusion, it is evident that cultivators should do all in their power to utilise all the sunshine possible, and the protection they possess added to careful thinning of boughs and fruit, and by giving liberal encouragement to the trees that crop, and not over-stimulating those that are barren.—(*Read at a meeting of the Horticultural Club by Mr. GEORGE BUNYARD, V.M.H.*)

EUPHORBIA JACQUINIÆFLORA.

IT is at this season of the year when the beauty of the few remaining Chrysanthemums is daily decreasing that any gorgeous display of floral beauty is bound to be more than usually appreciated. I do not recollect for some years having seen so pleasing a display as that made by a grand group of the winter-flowering plant under notice, together with their well-known relative the Poinsettia, as in the conservatory of C. E. Lambert, Esq., at the Manor House, Effingham, this week. Not only are these plants grown as successfully there as I have ever seen seen them, but the able gardener, Mr. G. Bristol, is an adept in effective grouping. Contrast these brilliant colours mounted in a bank with Arums, white Azaleas, Roman Hyacinths, and Freesias, with the graceful foliage of Ferns and Cyperus alternifolius, and you have an association the beauty of which is better imagined than described.

As the Euphorbia mentioned does not seem to be so generally grown as its attractiveness at this season demands, the few cultural hints I here-with append may be of use. Propagation is effected by cuttings. The old plants having ceased flowering, they may be laid on their sides and water withheld in any structure with a temperature not lower than 45°. At the end of six or eight weeks they should be introduced into a brisk heat with their stems intact; young shoots will soon appear, which, if taken off when about 3 inches long with a portion of the old wood attached, make the cuttings.

These are best placed singly in thumb pots in a mixture of two parts peat and sand to one of fibrous loam, plunged in bottom heat of about 80°. As soon as rooted more light and air must be given, a shelf near the glass with brisk heat and moist atmosphere being chosen; in this position the pots soon become filled with roots. It will then be necessary to transfer the plants to their flowering pots, the 6-inch size being most suitable. Care must be taken in removing them not to break the ball of roots, but shift them as nearly as possible without disturbing the soil.

The compost should be formed of two parts good peat, two parts loam, to one of sand. The plants ought then to be placed in a light house or pit with warmth and a fair amount of sunshine, shading only for an hour or so from the midday sun. In August shading may be altogether dispensed with, and they may be plunged in cold pits or frames, so that their growth may become well matured, as upon this in a great measure the size of the bloom depends. A little stimulant may be given once a week when the pots are full of roots, withholding gradually as the flowers develop.

In September the plants should be removed into the house and syringed daily, not only to keep down mealy bug and other insect pests, but to promote free and healthy growth. Under this treatment sprays of bloom may be produced from 10 inches to a foot in length, and the plants become well worthy of the attention bestowed upon them. The enclosed sprays are forwarded as samples.—W. R. G.

[The sprays are bright, broad, and beautiful, and highly creditable to the grower of them.]

APRICOTS.

(Continued from page 31.)

PROPAGATION.

I DO not know what effect the stock has on the Apricot, beyond the fact that seedling Apricot stocks do far away the best on warm sandy soils. Moorpark and Peach Apricots come true from seed, but that is no reason why seedling Breda, Blenheim, or Shipley's should not be used as stocks. The stones ought to be sown as soon as ripe 3 inches deep in light rich soil, covering with a little litter in winter. After a season's growth lift, shorten the tap roots to 4 inches, plant in rows a yard apart and 2 feet from plant to plant. The stocks can be budded about the middle of June at 6 inches from the ground, not nearer and not much higher, and in another year we have maiden trees, the snagging being done before growth starts in the spring. The maidens can be headed in the autumn to about 12 inches from the ground, as there is then less danger of gumming.

There are Plum stocks, Mussel, St. Julien, Brussels, and Black Damson, but I could never make out which was which, except the "riders" evidently on Brussels, by the looks of the worked trees; and as for report, those stated to be on Mussel and Brussels were the healthier, the St. Julien and Black Damson manifestly liking a stiff soil—not one for Apricots. The trees gum fearfully, and no one ever ought to plant a gummed tree. The reticence of nurserymen about stocks, especially for stone fruits, is very noticeable. Will any knifeman kindly say what influence the stock has over the scion? for though the latter may overrule the former, there is often such difference between trees on assumably the same stock, that either these are themselves unhealthy or the scions must be full of disease plasma. Of all the questions appertaining to horticulture that of stocks is least understood by those having to produce fruit, and no one steps in the arena to elucidate the subject in a practical manner. In other fruits we know exactly on what stock the trees are, and thus can act according to requirements and of the fitness of trees to soil and position; why not in Apricots?

TRAINING.

The fan shape only is suitable for the Apricot against walls, and the greatest blunder made is in originating the branches too closely together, so that they join against each other and give rise to gumming. Keep, therefore, at least three fingers distant between the side branches of the young tree, and though this means but three, or at most five, branches the first year the distance best serves in the end. Any number of branches can be secured by pinching the central growths in June, and these will ripen sufficiently to withstand the severest weather, against walls. I hardly know how to describe the training of an Apricot tree against a wall, but it may be explained as a desire to cover the space equally from bottom to top in the shortest time. The main growths are trained in full length, and side shoots push so freely that there is seldom any difficulty in filling up the spaces between the main limbs.

Thus in summer the shoots are trained at certain angles upward, and the whole area is occupied as the trees advance. It is an art of covering space with branches at certain distances, with side growths between them for bearing. About two trimmings suffice—namely, one about midsummer to regulate the growths over the surface, and cutting back to two or three leaves shoots not required. Nothing could be more simple. The winter pruning on the old-fashioned lines is done in the early spring, the buds then swelling, useless growth cut out and the most promising retained, forerights and refractory spurs being shortened or cut clean away. It is useless to tell an Apricot grower of the old school that this would be better done as soon as the trees are cleared of their fruit, all superfluous shoots being then removed, any excess of growth left on the shoots cut back, and every effort made to perfect the wood. This all goes for nothing, and certainly is better left alone when it results in forcing growth instead of solidifying that already made. Truly, the go-as-you-please and spare-knife treatment suits the Apricot, health going with the extension, and the reverse, with gum, to the restriction system. Beyond this we need not further proceed at present, as the chief points are to plant the trees, train them so as to cover the wall space, and then the fruit will come if the other conditions are favourable.

PROTECTION.

The most unfavourable circumstances are those of the weather at flowering and setting time, especially in low-lying districts, as a night's frost may destroy the prospects for a year. The spouting of dwellings, kept in a proper state, act as sort of coping, and a double thickness of herring nets, secured to the brackets of the spouting, and let down in front of the trees to within 18 inches or 2 feet of the ground, securing there and taut, usually affords the needful protection; indeed, I have never known this simple mode of protection fail to efficiently resist the radiation of heat and the keeping at bay of frost for the safe cropping of Apricots on cottage walls. There is the heat and dryness of the wall as compared with a garden wall, and this, with free access of air at all times, implying a sturdy and hardy blossom, goes a long way with the Apricot. The netting also comes in handy for protecting bush fruit against birds, so that, all points considered, nothing better can be advised for cottagers and farmers than old herring nets.

Nevertheless, cottagers often have recourse to means that few would think of service. Twiggy sticks, such as Hazel, can be utilised similarly to herring nets, securing the sticks so as to form a sort of network, thickest at the upper part of the wall, but all over some of the twigs in front of the blossoming trees, and this sieve-like protection alike

prevents the heat radiating, and the cold from coming in to the trees. I have known the easy plan answer on a cottage wall when trees on the garden wall near by have been practically ruined by a protection of evergreen boughs. The Apricot blossom wants air and light, and these secured a little protection serves better than much.

Another plan used by a farmer who had poles for nothing was to place these just under the spout and in a channel cut towards to the wall 6 inches deep, 18 inches from it at the base, the poles being 4 feet apart and secured by soil at the foot. Soft straw bands were then twisted, stout, medium, and thin, and the first placed topmost next the spout of the building, running with the wall and about 6 inches apart; the next lot similar, and likewise the lower lot, all secured to the poles and drawn tight. The straws stuck out from the bands, and being hollow formed excellent non-conductors of heat and protection. The thickest bands were not more than two fingers in diameter, the medium about the thickness of the thumb, and the small equal to the stoutness of a finger. The bands told a tale, not in one year, but during the lifetime of the farmer, who planted the trees during the year of his marriage, and his son of three decades followed in his steps, the two trees occupying an area of 20 feet by 18 feet each, and bearing respectively 100 dozen fruits—choice Moorpark, which, at the wholesale price of 1s. 6d. per dozen, realised £15, besides supplying the requirements of the household.

I have seen cottagers improvise old sheets, anything handy, on sharp frosty nights to hang in front of the Apricot trees, and those not afraid of a little trouble, horny hands, and practical brains, always had Apricots when, as before stated, there were but few in the parson's or squire's gardens, the produce ever being in demand by the ladies of the large residences near. They prefer home-grown produce, and only buy Apricot concoctions in pots now because the home supplies are alike uncertain as inadequate. The copings of garden walls, and the poles with woollen netting or scrim canvas contrivances for letting down and drawing up by means of pulleys, are hardly the sort of thing to recommend for cottage and farmhouse walls, for besides the first cost and the requisite daily attention, there is little use for them during the remainder of the season, hence they are not advised where remuneration is the prime object, the simpler means of protecting being better and efficient in a generality of seasons. Whether the expense of such contrivances has anything to do with the abandonment of Apricot culture on walls may be a moot question now that so many gardens are really market gardens. I make no question of glass copings being the best for garden walls, and with coverings suspended from them, and drawn up in the daytime, there is no reason why Apricots should not be grown in gardens at a liberal return in produce for outlay in material and labour. In certain localities glass cases may be necessary, but this is a phase of the subject only referred to incidentally in the case of endeavour to grow more for the love of things than for profit, as neither the wall nor the soil suits in a majority of cases. We know gardeners can do anything they set their minds on, but unless we get a dwarfing stock for Apricots, or have such dwarf and prolific growers as Kaisha, it is worse than useless planting Apricot trees against ordinary garden walls for marketing.

The protection should not be applied until the trees are starting into bloom, it being better to lose the first flowers than attempt anything in the way of coddling. When the first flowers, however, are fully open, then is the time to put up the nets, sticks, or haybands; and once up let them abide until the trees have produced leaves, and these form a natural awning against frosts. This will usually be some time in April or early in May, the late frosts seldom having any effect on Apricots but the coddled under thick coverings, and then as tender at the end of May as the others are hardy right along; but take off half the netting, sticks, or straw ropes at a time, always commencing the reduction in mild weather, and the final clearance under similar conditions.—G. ABBEY.

COLOURED LIGHTS AND PLANTS.

UNLESS exposed to sunshine plants would never acquire their proper colours, elaborate their various secretions, or properly mature their seeds. This sunshine, or white light, as it is called, consists of several coloured rays, which are known to possess very different illuminating, heating, and chemical properties. Hence it has become a subject of great interest to examine and determine whether all these rays are alike in the development of vegetation. The solar beam of white light, when subjected to prismatic analysis, is found to consist of seven or more distinct colours—viz., orange, red, yellow, green, blue, indigo, and violet, all produced, of course, from a mixing or mingling of the three primary colours—red, blue, and yellow.

Of these the red rays evolve the greatest quantity of heat, the yellow the largest amount of light, whilst the blue produce the strongest chemical effects. It naturally follows, then, that by the use of glasses of these colours the natural conditions of a plant may be very greatly altered, for heating rays may be admitted whilst light and chemical effect are excluded; or light may be given whilst heat and chemical effect are withheld; or, lastly, the maximum chemical power may be afforded without exposure to light or heat. Seeds and plants treated thus furnish the following results:—

Under yellow glass the germination of seeds was prevented, or if it took place the plant soon died. Agarics and the fungus tribe generally flourished luxuriantly under the influence of the yellow glass. It is thought that although the luminous rays are injurious to vegetation in its early stages, in the later developments they are really essential to the formation of woody fibre. Under red glass germination takes place if

the seeds are properly cared for. Such plants, however, are unhealthy, and the leaves in a measure blanched, showing that the production of the chlorophyll or green colouring matter had been prevented or interfered with. Most vegetables, instead of bending towards a red light, as they do towards a white one, bend from it in a very remarkable manner.

Plants in flower can be preserved for a much longer time under the influence of red light than any other, and scientists opine that red media are of great benefit during the fruiting of plants. Blue glass has the power of altering the free passage of all chemical rays, whilst it obstructs both the heat and light radiations. The rays separated from these latter have the power of accelerating in a marked degree the germination of seed and subsequent growth of the plant. In fact they become too stimulating. This being discovered, plants removed into yellow rays, or, better still, into light which has passed through a green glass, were found to deposit more carbon, and consequently formed woody fibre in a regular and proper way.

Thus it follows from these evidences and like results that the germination of seeds in spring, the flowering of plants in summer, and the ripening of fruits in autumn, are dependant upon the variations in the quantities of actinism or chemical influence of light and heat, at those seasons, in the solar beams.—WM. NORMAN BROWN.

MILDNESS OF THE SEASON IN SCOTLAND.

NATURE is at present in an unusually mild and amiable mood. The winter has been one of quite exceptional geniality, and plants of every kind in South-Western Scotland are in a very advanced condition. Should existing atmospheric influences continue to prevail without any intervening visitations of frost, fruit trees are likely to have an abundance of blossom, especially as—partly owing to the destructive storm in June of last year—they have had an exceptionally long period of repose. At the present moment the horticulturist has reason for self-congratulation, but it is much too soon for confident hope, which becomes not seldom during the early months of spring “near neighbour to despair.”

Though the Snowdrop appears to be somewhat late with Mr. S. Arnott this season, it has bloomed in my garden quite as early as usual, if not indeed somewhat earlier than it came last year. During the dreary period that has intervened since the latest variety of the hardy Chrysanthemums disappeared from our vision my chief consolation has been *Jasminum nudiflorum*, one of the sweetest and gentlest, notwithstanding its heroism, of winter flowers, and it is still flowering exquisitely, with the Snowdrop at its feet, on a sheltered north wall. The most attractive flower on the south wall of my garden, where it is at present growing with great rapidity, and will ere long be unfolding its tenderly beautiful, Snapdragon-like, miniature flowers, is *Linaria cymbalaria*; of which, in his comprehensive work on “The Natural History of Plants,” Herr Anton Kerner von Marilann has expressively said: “It raises its flower-stalks from the stone wall over which it creeps towards the light; but as soon as fertilisation has taken place, these same stalks, and amid unchanged external conditions, curve in the opposite direction, so as to deposit their seeds in a dark crevice.” Notwithstanding its peculiarly refined and fragile aspect, few flowers have such a strong constitution as this. Equally remarkable is its rapidity of growth.

Almost for the first time within the range of my remembrance I have fragrant *Auriculas* at present in bloom. It is seldom indeed that their flowers appear in my garden before the month of April, of which it is undoubtedly, especially in the matter of fragrance, the predominating attraction. *Prunus pissardi* is forming its flower buds, and signs of activity are visible along the branches of the Almond tree. *Andromeda floribunda*, whose classical name was conferred upon it by the great Linnæus, and which belongs to the Ericaceous family or order of plants, will soon be in flower. Rose trees, inspired by the mildness of the season, are throwing out prematurely their graceful shoots crowned with buds that will never develop into their possibilities of beauty for lack of the generative influence of the sun. As an accomplished rosarian said to me in one of his letters, written during a very similar season, “Like naughty children, they will not go to sleep.” It would be better for themselves, in all probability, if they sought repose.—DAVID R. WILLIAMSON.

F.R.H.S. AND SO FORTH.

AM I as a Fellow of the Royal Horticultural Society entitled to place these initials as an affix to my name, or not? That is the question. Those who are recipients of the medal of honour may use the initials V.M.H., but they must do it in fear and trembling, lest they incur anathema, or reprimand. But how stands it with the F.R.H.S.? I have been induced to ask this question because I could but notice, when looking over, as published in your columns, the lists of the new Committees of the R.H.S., that whilst nearly every member of that very learned body, the Scientific Committee—there are thirty-four of them—has the initials of some society after his name, not one, even the undecorated, has F.R.H.S. Are these learned societies' fellowships so very dignified that they are thus paraded, or are those of the R.H.S. so much the reverse that they are not so employed? Possibly it may be said that as the Committees are those of the R.H.S., and as only Fellows are eligible to be members of these Committees, to attach F.R.H.S. after each name would be superfluous. That may be so, but where some initials are so paraded why not others?

What is so curious, too, is that whilst fellowships of three Societies only are recognised, yet affixes quite as honourable, not even the V.M.H., are attached to any member of the other four Committees. That is more than curious—it is funny. However, to revert to the question raised above. I notice in one case of a Fellow that his chief local paper dubs him F.R.H.S. under all circumstances. May that be regarded as O.K., or, as translated by Justice Ridley, “all correct?” I feel an interest in knowing, and my interest—originally whetted by a recent pronouncement with respect to the use of V.M.H.—is doubly so by the publication in your columns of these wondrous scientific fellowships and the absence of the horticultural ones. Is it no honour to be identified with horticulture, and is the old art on the down grade after all?—A FELLOW.

[This “Fellow” may compose himself. Horticulture is in the ascendant, and for the first time in history is used as a flag, in the form of large posters, under which distinguished botanists and scientists, who are not horticulturists, are sailing on their lecturing voyages. This admission of the attractive power and influence of horticulture is significant, and our friend ought to rejoice in the compliment thus paid to the ancient art to which he is devoted.]

THE YOUNG GARDENERS' DOMAIN.

GLADIOLUS THE BRIDE.

THESE, like so many other bulbous plants, are easy to grow, and desirable in every respect; and where cut flowers are in demand they should be found in quantity, as they well repay the care and attention that must be afforded them. The most essential point to insure success is to have well-ripened corms, for if they are not properly matured they will flower indifferently, and not give satisfaction.

The best mode of culture, which if given a fair trial will commend itself to all, is the following:—Enough corms should be procured to make two successions of a size according to the requirements of the grower. The earliest ought to be potted in the autumn, and grown to produce flowers during the following spring and summer; 5 and 6-inch pots, clean and properly drained, are most suitable. If the roots are the size of a shilling, six for the former and nine for the latter will be ample. Pot firmly an inch below the surface in a mixture of two parts sandy loam, one part peat, and one part leaf mould and sand. Plunge the pots to the rim in ashes, and water sparingly until they push through the soil. Keep them growing in a cool temperature until about February, when a few pots may be introduced into an intermediate house at intervals to make them last over a longer period. As soon as they have done blooming and show signs of ripening harden them, and place the pots out of doors on their sides, gradually withholding water as the leaves ripen. Care should be taken to protect them from heavy rains afterwards, or the bulbs will decay. When ripened they should be shaken out and laid thinly on a dry sunny shelf for a time, eventually storing them in a cool place, free from frost, until the following March, when they can be planted as advised below.

The succession should be planted in March, in rows 6 inches asunder and 3 deep, on a south or west border, with a deep well-worked soil. They are greatly benefited by frequent hoeing and a mulch of short manure. They can be lifted in September, tied together in bunches, and hung in airy houses to become well ripened, and afterwards potted as advised for the earliest corms. It will be seen by the above methods they are grown in pots and in the open ground alternate years, and being sound and well matured will consequently flower much better than if grown in pots, as is often the case, every year. It will also be noted that flowers can be cut from those in the open ground, and used for the various purposes for which these lovely spikes are invaluable.—NIL DESPERANDUM.

SCHIZANTHUS.

WHERE cut flowers are in constant demand a gardener has to exercise judgment as to those kinds that are best and most useful for that purpose. Some of our choicest flowers would prove an utter failure (though they last well on the plant) if they were used for vase work. *Schizanthuses* are admirably adapted for cutting, and are not difficult to grow if not allowed to become drawn while in the seed pan.

A good time to sow the seed is about the last week in August when the plants are wanted in flower in the following spring. It should be sown thinly in well-drained pans, using a moderately light soil. On a shelf near the roof of a greenhouse is a good place to stand the pans till the seed have germinated. A sheet of paper may be laid over them for shade. As soon as the young plants appear the paper should be removed, so that they may have all the light possible.

When the seedlings are large enough to handle pricking them off becomes necessary. It is a good plan to transfer them to boxes for a short time, after which they may be potted in small 60's, using a little heavier soil, and keeping them in a cool temperature. About the end of January they must be shifted into the flowering pots, care being taken in giving them good drainage. As a rule 24-size pots are used, placing four plants in each. If 32-size are used two plants in each are sufficient.

When the plants begin to make rapid growth, as they generally do, they should be given a stake, or they soon fall over, and the growths become cramped. *Schizanthus* never require more than an ordinary greenhouse temperature, and I think if this were more generally recognised they would be much more largely grown. If the foregoing cultural notes prove a benefit to any of my young fellow craftsmen I shall be gratified.—ASPIRANT.

HARDY FRUIT GARDEN.

Pruning and Training Apricots.—During open weather in the course of the next few weeks the necessary attention must be given to the requirements of Apricots on walls. The pruning out of old useless branches or growths is the first essential, next the reduction of the young shoots, so as to leave no more than may be accommodated on the wall without crowding. Those shoots not wanted may on the lower side be cut out entirely, on the upper shortened back to form artificial spurs.

There will also be found a number of natural spurs, all of which must be preserved, for, providing there are sufficient of these, artificially formed spurs are not required. Fruit is borne on both these kind of spurs, as well as on young shoots, and the object of pruning should be to so regulate these bearing parts that the wall may be effectually, but not thickly, covered. Young shoots, before being nailed in finally, ought to be pruned to a wood bud singly placed, or to one situated between two blossom buds, termed a triple bud.

All the branches must be displaced from the wall and re-arranged, especially if worn out parts have to be removed, thus causing large vacant spaces. Young vigorous shoots from near the base ought to be selected for filling up the spaces, but if not practicable secure those in the most convenient positions. Strong but not sappy wood is the best to utilise.

Peaches and Nectarines.—These differ little from Apricots in the matter of pruning, training, and general management. There is a difference, but it lies chiefly in the freer utilisation of the young ripened wood of the previous year, relying less on either natural or artificial spurs.

If summer and autumn pruning were judiciously carried out at the proper time, there will not be much superfluous wood to be removed now. Weakly or worn-out branches it is requisite to dispense with, and this may occasion the complete readjustment of the branches. In all cases it is necessary to clear out the old bearing wood of last season, and if this were not cut out in autumn it must be done now. The best shoots for retaining are those laid in below the bearing shoots of the previous season. They require to be well ripened and situated on the upper parts of the secondary branches. If the points are unripe or there is not room for full length shoots, cut back to firm ripe parts, but to a position where triple buds are situated, or at least to a single wood bud. This is an important point in the pruning of Peaches, Nectarines, and Apricots, because if a shoot capable of bearing fruit is pruned to blossom buds no wood growth can extend beyond the fruit, hence no flow of sap is maintained to support the fruit, which consequently dies.

In nailing in the wood, first secure the principal branches, disposing them regularly over the space at command, next the secondary branches, and lastly, the young bearing shoots, laying them in evenly at a distance of 6 inches apart. Avoid making shreds too tight, and placing nails so that they are liable to injure swelling shoots.

Though it is desirable to have the training completed before the trees commence blossoming, yet it is advisable to delay the final nailing as long as possible, in order that the expansion of the flowers may be retarded, especially if mild weather prevails.

Cleansing Walls and Trees.—After the training has been completed, should the flowers not be too advanced towards opening, trees that have not been seriously affected with red spider or scale during the previous year, may be effectively cleansed by a thorough syringing with a solution of softsoap, 2 ozs. to the gallon of water, with the addition of a handful of sulphur mixed in. The sulphur will combine better with the solution if mixed into a paste first with a little water. The walls will be cleansed as well as the trees, but if the mortar has fallen away from between the bricks, fill the spaces up before re-arranging the trees. Where there is any possibility of red spider hibernating on the stems, branches, or shoots, the trees should be painted over with a mixture of Gishurst compound, 6 ozs. to the gallon of water to which has been added soot, clay, or loam, making the mixture of the consistency of paint. Apply this dressing with a painter's brush, laying it on the young shoots very carefully from their base to extremities, so as not to dislocate the buds.

Young Wall Trees.—Trees newly planted in autumn, and only loosely secured for allowing the trees to settle with the soil, may now have the pruning needed, cutting back to suitable buds, the shoots regularly disposed and nailed in. Providing there are a sufficient number of well ripened shoots to form a good foundation of branches, unripe ends only may be pruned away close to wood buds. If there are not the proper number of shoots for forming the main branches, prune lower. Additional shoots will thus be originated of the required strength, selecting the best when extending to form the branches. Bold wood buds pointing in the desired direction are usually selected for pruning to.

FRUIT FORCING.

Pines.—The plants recently started into fruit will, if in good condition at the roots, produce strong suckers. When these are large enough to handle, all, except one to each plant, should have the growths checked by

taking out the centres of those not wanted. As a supplementary batch to the autumn-potted plants, select others which have been wintered in 7 or 8-inch pots, choosing the most vigorous plants. The remainder of such plants ought to be reserved until the general spring potting, when they should be shaken out and treated like suckers. Provide fibrous loam with the herbage reduced, or if used fresh it should be placed where it will be heated, so as to kill the grass and any contained larvæ, and when torn up add about a pint of superphosphate and a similar quantity of soot to each bushel of compost. If the turf has been laid up it must be had under cover some little time before using to become dried. Drain the pots moderately, but efficiently, dusting with wood ashes or soot to exclude worms, and keeping the plants well down in the pots, ram the soil firmly round the roots, leaving sufficient space for copious supplies of water being given when required. For Queens, 10-inch pots, and 11 or 12 inches are suitable for varieties of more robust growth. A temperature of 60° to 65° will be sufficient for these plants, also for those potted last autumn, and 80° to 85° at the roots.

Plants in beds about to be started into fruit must not have the heat at the base of the pots over 90° or 95°, or their roots will be injured. If sufficient fruit be started to meet the requirements, later successional plants may be advanced slowly, they, with autumn-potted suckers, requiring careful watering, especially where the heat is supplied by fermenting materials.

Strawberries in Pots.—The weather, though mild, has been foggy and unfavourable for more than keeping the plants gently moving. Ventilation must be very carefully given to plants in flower, setting or swelling the fruit, as sudden and drying currents of cold air start both the organs of fructification and the tender fruits, and they do little good afterwards. When the air is cold and sharp some hexagon netting placed over the ventilators admits of fresh air when it could not otherwise be admitted. Plants in flower should have air under or above them, so that it is warmed before it comes in contact with the tender fructifying organs. Have the atmosphere rather dry for a couple of hours each day, so as to insure conditions favourable for fertilising by a little extra heat if necessary, with freer ventilation. Fertilisation is easily effected with a feather duster, examining the flowers each day until there is a good crop set, after which remove all superfluous flowers, also surplus and deformed fruits. Water the plants in flower on the mornings of fine days, lifting the leaves and flowers with one hand so as to avoid wetting them, and keeping the water from the crown, as that frequently suffers through the frequent application of water and a close atmosphere. Afford liquid manure to plants swelling their crops, and maintain a genial condition of the atmosphere with a temperature of 60° to 65°, with 10° to 15° rise from sun heat.

Vines.—*Earliest Forced in Pots.*—These will now require copious supplies of liquid manure, always tepid and never too strong. The nourishment is required as soon as the Vines have made fresh growths, and then right along to secure well developed bunches and berries. When these are set, thin somewhat freely to induce fine berries, but not going to the extreme of making the bunches loose; compact, even-berried clusters are the most tempting. Maintain the night temperature at 60° to 65°, falling 5° on cold nights, 65° to 70° on cold days, 70° to 75° when mild and dull, and on fine days ventilating at 70°, but only a little, increasing the air with the sun heat to 80° or 85°, at which keep through the day from that source, closing in good time and so as to run up to 90°, then damping the paths and walls. Damping is also necessary in the early part of the day, and in the evening of fine days.

Early Forced Planted-out Vines.—Attend to tying the shoots and stopping them one or two joints beyond the show of fruit where space is limited, the axillary growths or laterals below the bunch being removed, except those on the two lowest joints, which, with those above the fruit, should be stopped at the first leaf and subsequently as made. The stopping is very important, for allowing more growth to be made than there is room for, and not considering that a little lateral extension is desirable, causes overcrowding, and that is fatal to good results. The cultivator must be guided by circumstances, and manipulate so that the principal foliage be fully exposed to light. Very close stopping is not advisable where there is room for extension, the increased foliage promoting corresponding root action, and the elaborating power is enlarged; therefore, make provision for an increase of growth, and retain all the foliage consistent with its full exposure to light and air. Maintain a temperature of 65° at night, and 5° more for Muscats where the Grapes are in flower.

Buckland Sweetwater, and others that do not set the berries freely, should be brushed over with a large camel's-hair brush or brush of feathers. This is essential for Muscats, assisting fertilisation by shaking the rods daily, or dusting the bunches (after brushing them) with pollen taken from varieties that afford it freely, and this, applied to the stigmas, usually results in a good set, especially if accompanied by a circulation of rather dry, warm air. Commence thinning when the berries are about the size of small peas, it then being seen which berries are fertilised by their taking the lead in swelling. Ventilate carefully, a little at a time, so as not to reduce the temperature, only to prevent its rising too suddenly and too high. Maintain a genial condition of the atmosphere after the Grapes are set by damping the paths and borders in the morning and at closing time. Water inside borders as required with tepid liquid manure not less in temperature than the house.

Vines Started at the New Year.—The buds are moving both evenly and strongly. Continue syringing the Vines twice a day until the bunches form, then discontinue it; maintain the atmosphere afterwards in a genial condition by damping instead two or three times a day. Avoid syringing hot-water pipes when highly heated, the vapour being different from the

moisture given out by cooler surfaces, and is a common cause of rust. The temperature should be increased to 55° at night, and 60° to 65° by day, with an advance to 75° from sun heat, gradually raising the heat to 60° to 65° at night, and 70° to 75° by day by the time the Vines are in leaf. Ventilate carefully, early, and in accordance with external influences.

Houses to Afford Ripe Grapes in July.—The Vines must be started early in next month. There is no need to cover the outside border with more than a light mulching of lumpy material to prevent snow or frost chilling the roots. If the Vines are planted outside protect the stems with hay-bands. Syringe the Vines two or three times a day, maintaining a night temperature of 50°, and 55° by day, with 65° from sun heat. Supply inside borders with water or liquid manure in the case of weakly Vines, always equal to the mean of the house in temperature, and never making the soil sodden, yet bringing it into an evenly moist condition.

Late Houses.—Gros Colman, Gros Guillaume, Mrs. Pince, Trebbiano, and other Grapes requiring a long time to grow and perfect their crops should be started about the middle of next month; therefore have the houses put in order, and everything essential in respect of cleanliness to the Vines doing well effected without delay.

THE BEE-KEEPER.

BRITISH versus FOREIGN HONEY.

It will be interesting to bee-keepers to know the value of honey imported into this country during the past year. According to a return furnished by the Statistical Office H.M. Customs, honey to the value of £22,061 was imported. In 1896 the value was £29,296, and in 1895 honey valued at £41,302 was imported. It is not possible to obtain the correct weight of honey, the value of which works out to the above figures. It will, however, be considerable, as the price quoted in the first instance would be low.

An object lesson to bee-keepers in this country, which they should not lose sight of, is the gradual decrease in the imported article. It would be much more satisfactory if the weight of honey were known, as the value may have been less per ton during the past year than in previous years. But this can hardly account for the difference of £19,241 in two years.

As the decrease has been gradual, and there has been no particular reason to account for the falling off, we can only come to one conclusion, which is that bee-keepers throughout the country are producing honey of superior quality, and in much greater quantity than formerly. This is encouraging to those bee-keepers in this country who have steadily worked on simple, but safe lines, and encouraged others on the same course in the use of the modern moveable frame hive. The above figures will doubtless come as a surprise to many people, as neither of the past three years has been really good for honey production. There have been a few isolated cases in which large yields have been chronicled, but they have been in the minority when compared with those who had a fair or indifferent harvest.

Although in some districts there has been a general falling off in the number of bee-keepers, many of whom kept their bees in straw skeps, and lost them through disease and carelessness, their places have been more than filled by those who have managed their bees on rational lines in the moveable frame hive. The result is shown above, and should act as an impetus to try and further reduce the importation of honey into this country in the future.

HAVE PRICES ADVANCED?

It is sometimes remarked, "figures may be made to prove anything;" and this is partly true, as they are sometimes misleading, still one cannot ignore the fact that there are now many tons of honey obtained in this country from districts where a few years ago it was all wasted, as there were no bees kept to collect the nectar from the flowers; or what bees there were had made their homes in the roof of some old building or in the trunk of a hollow tree, whilst here and there, often two or three miles apart, were to be found the homely straw skeps. Honey was not in demand, owing often, we fear, to the inferior samples and the rustic manner in which it was offered. Prices were high, and the foreigner was not slow to observe the opening for his product.

Honey in various degrees of purity, tastefully put up in glass jars, and neatly labelled, was to be found in all our provincial towns. The get-up being good, and prices low, a ready sale was usually effected, although the quality was often doubtful. The British bee-keeper now came in with honey of superior quality, which was tastefully put up in screw-top glass jars. Comb honey, too, of spotless purity was met with in all directions, the result being as shown above, the gradual ousting of the foreign product from our markets.

Prices, though, are lower than they were a few years ago, but there has been no perceptible difference in the price of either run or comb honey during the past seven years. The large dealers in our towns

practise the maxim of "small profits and quick returns," both comb and run honey being sold retail at the same price throughout the year. There is no prospect of prices being higher, neither are they likely to become much lower, except for inferior samples. The many inquiries for really good honey during the past few months gives one the impression that it is somewhat scarce, and that prices may harden.

SENDING COMB HONEY BY POST.

The parcels post is a great convenience to bee-keepers, as they are thus enabled to send small parcels to friends or customers much cheaper than would be possible by any other means. Great care, however, is necessary in packing comb honey, or it will not arrive at its destination in good condition. Not more than half a dozen 1 lb. sections should be placed in a box. If more is required they will travel much safer by rail.

If the sections are double glazed they will travel admirably if some soft paper is placed between the face of each section. Sufficient should be used to prevent concussion if the package has rough usage. A layer of hay, dry moss, or something of a similar nature, must be placed at the bottom of the box, which should be slightly larger than required for the sections. The intervening space at the top and sides must be well padded with the same material as placed at the bottom of the box. If the sections are not glazed, place a piece of cardboard slightly larger than the section against the face of the comb. The ends may lap over the sides and tied with a piece of string and packed as above. The whole should be packed firmly, so that there is no possibility of the sections moving. Fasten securely, and place a red label on the top of box marked "Fragile," and if the sections are placed in the box in the same position they occupied in the hive, they will travel a long distance without damage.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

* * * All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8. Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Packing Flowers (T. B.).—The box had either been sent off without any string round it, or it had been tied so insecurely as to escape. The lid had evidently been off, and the contents crushed in roughly among dry paper, the flowers separated from the stems, shrunk and curled into a ball. It is a matter of surprise that they reached us at all. We are trying to revive them, with the object of giving the name, if possible, next week.

Small Tomato Plants Withering (Cross).—The slight withering of the tips of the leaves in some of the plants may have been caused by sulphuring the adjacent houses, also the general yellowish colour of the foliage, but there are no disease or micro-organisms. The general weakness is due to thick sowing or drawing of the plants in the early stages. They are, as you say, weak at the roots. This you particularly ask about. The microscope revealed a few mycelial threads of some fungus, perhaps *Fusarium lycopersici*, but no "sleepy disease." The fungus may or may not have had something to do with the decay of the tap root, but there does not appear to be anything to be alarmed about, except the weakness of the plants; and as for the fungus, a little air-slaked best chalk lime sprinkled on the surface of the pots, just a light dusting, would be likely to subdue it, as the first watering would wash the lime down. The plants will no doubt improve as the days become longer. They cannot be too near the glass, affording air liberally, yet judiciously, on all favourable occasions, and not watering more than is needful to prevent flagging, as overwatering hinders root formation, which must be encouraged. We should raise the plants very differently, and expect them to thrive.

Certificated Radishes (S., Northampton).—The two Radishes to which you refer are "Deep Scarlet Olive-shaped Extra Early" and "White Olive-shaped Extra Early." We take the names from the "Journal of the Royal Horticultural Society," vol. xxi., part 1, August, 1897, where it is stated they were certificated unanimously at a meeting held on April 21st of the same year. It is also stated in the report that "these two Radishes were proved to be the earliest of all, and were ready for use in five weeks from the date of sowing." They were grown at Chiswick from seeds supplied by Messrs. Vilmorin & Co., Quai de la Mégisserie, Paris.

Peach Buds Falling (W. S.).—Your statement that "the trees were very dry at the end of autumn" is quite sufficient to account for the buds falling now. We have frequently used the same insecticide that you have, and never with any such untoward results, and we can only conceive it proving injurious when applied at an excessive strength or in a rough manner. Possibly, if you dig down deeply enough, you might find dry soil now; but be that as it may, dryness at the roots in the autumn is a fertile cause of Peach buds falling at this period of the year. We hope they are only falling to a limited extent, or equal to a thinning, and that sufficient will be retained for insuring a crop of fruit.

Violets in Lancashire (Aigburth).—Your mention of Widnes reminds of sulphurous fumes, and where these prevail Violets cannot possibly be grown so well as where the atmosphere is pure. They rank amongst the worst of all "town garden" plants, because so susceptible to injury by atmospheric impurities. Moreover, soils exert a great influence. We know of a district in Sussex, in view of the English Channel, and the air pure, where Primroses luxuriate; but not a Sweet Violet can be found in the banks for miles, and only here and there, at wide intervals, is the scentless "Dog Violet" seen. It is practically impossible to grow Sweet Violets in gardens in that district; and if they are not found wild in banks in any locality, while they flourish naturally in another, we should say it is impossible to make them succeed equally in gardens and frames in both districts. Violets sometimes, or often, fail in frames through not having been removed to them from the open ground soon enough. Given healthy plants prepared in gardens, it makes all the difference in results by those plants being planted in frames during the first week in September and the last week in October. We should not expect Violets to thrive within the smoke radius of Widnes half so well as in certain districts of "Essex and Kent."

Books for R.H.S. Examinations (T. B.).—If you write to the Secretary of the Royal Horticultural Society, 117, Victoria Street, Westminster, on the subject, he will send you a list of books recommended; but we have to say that large and expensive books have not been found the best by candidates who have told us that they deeply regretted they had expended hardly earned money on them. One of these candidates, who headed the list a few years ago, told us that he had thrown £3 away on "big books," and he found the compressed information in the cheaper primers and manuals of far greater use to him than the large volumes through which he had to "wade" for hours and sift the chaff from the grain as he went along. As to the "subjects dealt with," no one knows what they will be until the envelope containing them is opened in the examination room. Several of the questions may be of a strictly scientific nature, some of them mere puzzles, others practical and useful; but each candidate can select the number that must be answered from the list. On these he must concentrate attention and do the best he can with them within the time allowed, ignoring the others. You must understand it is not those who possess the most really useful practical horticultural knowledge who win the most marks in these examinations in "horticulture," but rather those who have a smattering of knowledge on many things, and who are apt in making the most of what little they have in the time at disposal by expertness in the use of the pen. You have heard of the "pen being mightier than the sword." It is more powerful than the spade in these "exams," and the most effective and profitable workers may find themselves far behind, in the number of marks, those who if placed in a garden for producing supplies of the best fruit, flowers, and vegetables at the times required would utterly fail. The questions asked are as much, if not more, botanical and scientific as practically horticultural. Some we have seen were not in our opinion worth the paper they were printed on, so far as they had bearing on the occupation of useful gardening; and we are as certain as we can be of anything that neither of the examiners who propounded the questions could, if confined separately in a room, answer the whole of them—practical and scientific—in a manner to entitle them to a place in the second-class list. Each could answer his own, of course. The point is that each candidate should not only do all he can to become well grounded in the scientific principles and practical routine of gardening, but must also cultivate the art of free and correct expression—a matter of considerable importance in the equipment of a gardener who expects to occupy and fill creditably a prominent position, such, for instance, as Mr. David Thomson occupied for nearly thirty years at Drumlanrig, and Mr. Owen Thomas fills so well in the Royal Gardens, Windsor. They might be able to grow the best of Cabbages and other things, but this would not suffice by a very long way, apart from other accomplishments that go to make a really high-class gardener. You may well remember that these exams. are not in the ordinary sense of the term competitive. Every candidate is accorded the marks to which he is entitled, and if he does not win so many as he hopes at the first attempt, he should try again. We see no reason why you should not put your abilities to the test, as you have nothing to lose and much to gain. Mark the questions, when you see them, that you feel you can best answer; apportion time to each of them, as if you answer, say, seven splendidly and forget the eighth, you may lose the medal, as happened not so very long ago.

Seedling Cypripedium (G. S.).—Your seedling is identical with *C. Lathamianum*, first raised by Mr. Latham, Curator of the Birmingham Botanic, and flowered by him in 1888. Similar results have been obtained by Messrs. J. Veitch & Sons from the same cross—namely, *C. Spicerianum* and *C. villosum*. Plants are now producing flowers in the Chelsea Nurseries of the firm just named exactly like the one you have sent, while others from the same cross show slight varietal differences. *C. Lathamianum* appears to grow and flower freely. The nearly white dorsal sepal, from *Spicerianum*, contrasts effectively with the other parts of the flowers, which are of a massive villosum-like character. The variety is worthy of extended cultivation.

Narcissus Tazetta Snowflake (T. A.).—The snow-white flowers, twelve on a scape, are charming in appearance, and both the bulbs and the treatment they have received must have been of the best. We perceive nothing unusual in the perfume for the variety. It differs from that of the Paper White in being heavier and, to our sense, less pleasant. We know of persons who cannot endure flowers of the last named in rooms, while others enjoy them. The perfume of the yellow cupped forms is totally different, some being distinctly sweet, and by many persons enjoyed, but not all. We do not think the odour of the flowers is materially affected by forcing; and, generally speaking, such as those you have sent could only be sparingly used in rooms.

Names of Plants.—We only undertake to name *species* of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*P. Taylor*).—1, *Adiantum macrophyllum*; 2, *Davallia Tyermani*; 3, *Cyrtomium falcatum*; 4, *Adiantum cardiochlena*; 5, *Davallia canariensis*; 6, *Adiantum formosum*. (*Grass*).—*Eragrostis elegans*.

OUR YOUNG SISTER.

ENGLAND, as a mother country, owns many daughters—in fact, it is perfectly true that the sun never sets on her dominions. Some of these daughters have lost their first youth, one daughter lost to us for ever through our own foolish management; forgetful of the fact that the part of N. America now styled the United States had got out of leading strings, we tried to impose upon her burdens and restrictions she would not bear—she rebelled, and we lost one of the fairest jewels of our crown. We learned a lesson then, never to be forgotten, and we have since tried to remember that children grow up, and must be allowed a little exercise of their own judgment. A harsh, unjust parent compels disobedience; then follows rupture, and the loss to both sides is great.

Among a small community there is often expressed an opinion that England's large family cripple her. Never was there so narrow-minded a mistake. An infant colony at first cannot walk alone, but let that colony be well nourished it soon outgrows childhood, and becomes at once both a strength and a glory. Her markets provide an outlet for our manufactured goods, and our markets are only too ready to receive her raw material. Then again, too, ours is a teeming population, and the difficulty of finding employment for that population grows.

There are so many young ardent fellows who (even if they could get it) would find the office stools in the close City most irksome—who pine for the freedom of an outdoor life, and who gladly embrace such a life in a far-off country where the mother tongue still sounds in their ears. The agricultural colonies of Australia have always had a charm for us, partly from the fact, perhaps, that South Australia owed its colonisation to a near relative of our own, who developed its agricultural resources to an immense extent, and to the great benefit of himself and his family. We are referring now to S. Australia, but would turn our attention to N.S. Wales, an adjacent territory.

Have our readers any idea of the size of this the oldest Australian colony? We fancy not. Now for some idea of its size. The British Isles contain 120,849 square miles; N.S. Wales contains 310,700, or very nearly three times as much. Of course, the population is very, very much less—1,182,500 as against 37,879,235.

The first farm was started at Paramatta in 1789; but the farming most in vogue in N.S. Wales is stock breeding. The country was eminently favourable to this branch of industry, probably because stock are more easily transported to places of sale and consumption than any other commodity. The wool trade has always been a great standfast of these colonists; indeed, we should almost suppose that the wool industry has reached its zenith. Fifty-seven million sheep make a very respectable flock, and the annual value of their wool is something like 9 millions sterling.

It may interest some readers to know how very quickly wool degenerates in Australia—we mean the quality—and it is of the utmost necessity that fresh blood be constantly imported from our best English flocks. We have seen specimens of Australian native wool, then the wool after one cross, and so on till the fleece became a staple of great beauty and weight. Some of these fleeces have been exhibited both in Paris and at our Colonial and other exhibitions.

We find all these sheep have rather tended to diminish the cattle-raising; but as it is, we find there are about 2½ million head of horned stock. Here, again, we find the necessity there is of fresh blood from

home, and expensive as importation may be it pays. Herefords and Shorthorns do well in this country, which has really a climate not unlike our own. We remember long ago hearing much about the cost of freight, and how, in the case of cows, this cost was reduced to a minimum by sending over cows in calf, which were able to supply the ship's company with a fair supply of fresh milk *en route*.

The arable land of N.S. Wales is 1,325,964 acres, and the produce is about £2 11s. 3d. per acre. Now we think this is ridiculously small. Surely there is need of reformation here, or of new and approved methods. Poor worn out old England can do better than this, and here in N.S. Wales we have virgin soil. Wheat occupies 647,483 acres, and the crops must be very light, as the value of the Wheat harvested is only £2 5s. per acre. Much of it is grown for hay, a thing we never heard of before, and in this form the value per acre is about £3 10s. Poor as is this yield, it is equal to that of United States of America and Russia.

When a country has still some thousands of acres suitable for Wheat growing, and has to import 2,000,000 bushels for home consumption, there is need of reform somewhere. Maize, too, might be grown with success. As green food it is most valuable for cattle. And there are, too, cooler regions suitable for Oat cultivation. In the eastern districts we find what we should call here good butter grass, and the people have already established over 400 creameries; 26,000 hands are employed, and the output is about 30,000,000 lbs. Mr. Williams, from whose able paper we take these facts and figures, thinks the N.S. Wales farmer does not understand the proper winter management of dairy cows. Possibly cake is bad to come at, and dear into the bargain, and there may not be a good Mangold pie at command. He also finds more moisture in the butter than is desirable (whether water or buttermilk he does not observe). This might be easily remedied by the importation of a few of our young dairymaids armed with the latest butter workers from Museum Street, London.

We generally associate milk and bacon, but the bacon must be of first-rate quality, and possibly co-operation must be tried to bring any scheme of bacon rearing and curing to perfection.

Forestry hardly comes under the head of agriculture proper, and yet just a word may be said here as to the excellence and variety of timber grown in this colony. Mahogany is one of the native growths, and there are many others of great commercial value. Australia has a great future before her, and her value as a food producer for the world is immense. As science advances we shall receive of her superabundance, beef and mutton in more desirable forms than the tinned consignments of to-day, and her butter and cheese carefully manipulated may oust the Danish and American products out of the market.

We should fancy one great difficulty in Australia is the labour question and the distance from ports of embarkation; these are two evils that may be remedied.

WORK ON THE HOME FARM.

Mildness is still the chief characteristic of the present winter season. If the evening is frosty the morning is mild, and we are coming to the conclusion that there is little fear of severe frost this time. They must be keeping all the cold at Klondyke.

We are thankful to say we can do without it, but our strong land neighbours will hardly say the same, for without frost their spring corn sowing must be an expensive process, and far less satisfactory in finish.

Though mild, the weather lately has been dry, and we are only waiting for a dry windy day to attempt Wheat rolling. Rolling Wheat in January seems out of season, but handsome is as handsome does; and if the roller will work properly, the Wheat will no doubt be better for a little consolidation about the roots.

There is another thing: our light land is very subject to a weed called by various names, but most generally known as the common Poppy. This weed is never so easy to destroy as when it is very small, and we have already observed it amongst the Wheat in considerable numbers. It is now in its first leaf, and if it is to be effectually dealt with, the Wheat must be harrowed within three weeks; but there is a *sine qua non*—the Wheat must be rolled first, or the harrows will pull it up in large quantities.

A good thing for sand land Wheat, and very injurious to the Poppies, is common salt; but to deal with the weeds most effectually, the salt should be applied a week or two before the harrowing. If 5 cwt. of salt per acre be well and evenly sown, at the end of a fortnight a thin crust of caked soil will be formed on the surface. If the land be harrowed whilst in this condition almost every Poppy will be killed, its tender rootlets being snapped by the disturbance of the caked surface. The effect is practically the same as that of severe frost on a water-logged surface.

Wheats are looking fairly, but not so well as last year, and they are not so clear of twitch, for was not 1894 a rather wet season?

THE BLACK CURRANT.

ONE of the most useful of our "bush fruits" at the present time is the Black Currant, and though it cannot be compared with its relative the Gooseberry in one respect—namely, the length of the season during which its fruit is obtainable and saleable, yet it is extremely productive, and has hitherto been regarded as more reliable, owing to its hardiness and comparative immunity from disease or insect attacks. Whether the fruit is grown for home use or sale, it is, however, an important fruit, and a brief review of its history and culture may not be unacceptable.

Ribes nigrum is found wild in some parts of England and Scotland, occasionally, perhaps, being merely an escape from cultivated grounds, but in many cases, particularly in the northern parts of this island, it is probably a true native. Beyond Britain it is very widely distributed throughout the northern parts of Europe, extending into Siberia and the Western Himalayas; but though it is said to be found wild in North France and Italy, it does not appear to have been known to, or at least cultivated by, the Romans. Alphonse de Candolle, in referring to the antiquity of the plant, says, "From the variety of names" (M. de Candolle collected over forty names) "in all the languages, even in those anterior to the Aryans, of the North of Europe, it is clear that this fruit was very early sought after, and its cultivation was probably begun before the Middle Ages." In England it was cultivated at the end of the sixteenth century, as it is mentioned by Parkinson and other writers from that time onwards; but it does not appear to have been such a general favourite as either the Red Currant or the Gooseberry, as it is chiefly recommended for its medicinal qualities, and Leonard Meager (1699) says it is grown principally for its "physical" uses.

Forsyth (1806) implies that the Black Currant was somewhat of a favourite in Ireland, and mentions that the fruits are steeped in whisky, of which they make punch, and recommended it "as a good medicine for coughs and colds." He advises that the Currants be bruised and put in a jar, the

No. 2575.—VOL. XCVIII., OLD SERIES.

whisky being poured over them and allowed to stand for a week or a fortnight closely covered, then to be strained and put in bottles. It may be pardonable to refer to this, but I once had an opportunity in Ireland to try some "medicine" of the kind described, and it was undoubtedly both palatable and cheering, but whether that was due to the good quality of the whisky or to the Black Currants I have not yet determined.

It is a remarkable fact that the Black Currant should have been so long cultivated without producing any varieties, for in 1824 Loudon placed it on record that, "There are no varieties of the Black Currant." The author named in the previous paragraph (Forsyth) mentions, it is true, we have "the common Black and American Black Currants," but I have failed to obtain any explanation of this, unless the term "American" refers to some species, such as *Ribes floridum*, which bears black fruits. In "Loudon's Magazine" for 1828 a correspondent refers to a white-fruited variety of Black Currant which had been found in a cottager's garden near Bath a year or two before, but beyond that I have failed to find any record of an established variety until some years later.

The first edition of the late Dr. Hogg's "Fruit Manual" was issued, I believe, about 1845, and in it three varieties are named—the Old Black, Ogden's Black, and Black Naples, the author saying the second variety "is very fine and large, the berries measuring sometimes half an inch in diameter; the clusters are also much larger than in any other variety of Black Currant." This would appear to indicate that the author was acquainted with some not included in his list. Fifteen years subsequently (1860), when the second edition of the "Fruit Manual" was published, the same varieties are again the only ones named; but there are some corrections due to further experience, as it is there said of the Common Black, "This is much inferior to Black Naples and Ogden's Black, and not worth cultivation." Of Ogden's Black it is said, "This is not so large as Black Naples, but considerably better in every respect than the Common Black; the bush is hardier than Black Naples;" while of the last named variety Dr. Hogg says, "The berries are larger than those of any other variety, frequently measuring about three-quarters of an inch in diameter; milder and sweeter than any other Black Currant, and the best of all the black varieties." Black Grape is given as a synonym of Ogden's, and New Black as a synonym of Black Naples.

I have not succeeded in ascertaining the origin of the last-named variety, but in an American work by Andrew Fuller, published in 1867, it is described in similar terms to those in the "Fruit Manual," with the synonym "Cassis Royal of Naples." The word Cassis is applied to the Black Currant by the French, and has been used by most of the old writers, though an older name is Poivrier, and Groseiller Noir is also given by C. Bailey in his "Manuel du Jardinier," in 1829, with Cassis. Whether the variety Black Naples reached America from France I have not been able to ascertain, but it is the only clue research has afforded me. Perhaps some readers can throw a light on the origin of this Black Currant, as it is still one of the best in cultivation.

The eighth edition of the "Fruit Manual," issued in 1884, contains descriptions of two other varieties in addition to those in the preceding issues. Taking them in chronological order Lee's Prolific Black was raised, Dr. Hogg tells us, by Mr. George Lee, market gardener of Clevedon, in Somerset, and it received a first-class certificate from the Royal Horticultural Society in 1869. Further, after stating that the berries were "as large, or larger, than those of Black Naples," the author says, "This is by far the best of all the Black Currants." With regard to this I have in my memory examples of Lee's Prolific grown fifteen years ago, which exactly corresponded with the description in the "Fruit Manual," but the variety I have had or seen under this name within the past six years is much inferior to Black Naples; it does not grow freely, bears scanty crops, and the individual berries are small. In short, it seems to me that in some cases the common old Black has been distributed under this name. In the form I have obtained it Lee's Prolific is not worth growing, and Ogden's is little better.

The second variety alluded to is Black Champion, and I well remember when this was first shown by Mr. Dunnett at the meeting of the Royal Horticultural Society on August 9th, 1881, when the Fruit Committee awarded a first-class certificate for it. I measured berries that were over three-quarters of an inch in diameter, and the fruits shown were probably the finest examples of Black Currant ever exhibited. Shortly afterwards I had the opportunity of seeing the original plants growing in Mr. Dunnett's garden in Essex, and for vigour of habit, free bearing, and distinct rich flavour of the berries, the variety was all that could be wished. As seen then and several times subsequently, I should have had no hesitation in placing this variety before all Black Currants known to me; but unfortunately subsequent experience has been similar to that with Lee's Prolific, for though large berries are obtained from the variety I have grown under that name, they are not sufficiently abundant, nor is the plant of the free habit it should be to commend it to a grower who has to sell the produce. Whether this is due to deterioration or to inferior varieties being substituted for it I am not prepared to say, but in my experience I have seen special conditions or cultural methods result in great variations in the size of Black Currant fruit, nearly as much as there is between varieties. Some nurserymen regard Black Champion as identical with Baldwin's, but my plants of the former will not compare with this in growth or productiveness, though I know several market growers who have Baldwin's under the two names.

One variety which has come into cultivation since the last edition of the "Fruit Manual" is Baldwin's Black, already referred to, and which is said to have been raised in Kent, but as to the precise time of its introduction I have no certain information. It is, however, a useful variety, strong in habit, very prolific, somewhat earlier than Black Naples and with larger average fruit, and together they constitute all that any grower can require in Black Currants.—FRUIT GROWER.

P.S.—Since writing the above notes with regard to the Black Naples Currant I have referred to the "Hortus Duroverni," a catalogue issued by W. Masters, nurseryman, of Canterbury, in 1831, in which a list of Currants is given, and amongst them is the "Black" and "Naples Black," so that the variety would appear to have been in cultivation at least fifteen years before the first edition of the "Fruit Manual" was published.—F. G.

(To be continued.)

AMONG THE HARDY FLOWERS.

THE harvest of the gardener comes not in autumn alone. At all seasons he may reap some reward for his toil and care. Even the grower of hardy flowers alone may seldom be without the recompense given by the plants he cherishes. At times the harvest is scant, but it is his own fault if he is long without some flower to yield him delight. The dying time of the old year and the first days of the new are, perhaps, his fasting time, unless hard frost prevail when the longer days are well on the way. So now, in this mild season, the garden's dwellers begin to give more than a gleaner's share to him who loves them. Even with weather saddening to the optimist, and more than confirming the grumbling of the pessimist, the flowers have come on apace. They have sprung into birth as rose the Highland host on the hillside at the signal of Roderick Dhu. From mound of grey pink or green and Mossy Saxifrage Snowdrops and Crocus have emerged. The grass of the lawn, the meadow, and woodland are sprinkled or made white with the pendent blooms, or are gay with the coloured spires or cups of the Crocus. The Winter Aconite is more plentiful now than when last we wrote, and its cheerful little flowers have companionship in their yellow colouring now.

The glaucous grey-leaved Barbary Ragwort (*Othonnopsis cheirifolia*) has a few of its yellow flowers nearly open, looking pretty, as if set in a grey-coloured fluted cup. Yellow Crocuses are fairly plentiful now, for *C. gargaricus*, *C. aureus*, *C. ancyrensis*, and *C. vitellinus* are all in bloom. Some of the pot Marigolds have not been vanquished by the winter's days, and with a *Doronicum* or two keep up the colour's claims. Snowdrops are plentiful, and the eye is delighted with their charms of purity and form. Their beauty is not challenged, but their place in our hearts is not uncontested, for the Snowflake has come to draw us to admire its beauty and its grace. The varieties of *Erica carnea* have not yet reached the zenith of their beauty, but

before long *Erica mediterranea* will be in bloom as a rival in our affections. The pink *Hepaticas* are beginning to flower, too, and with the crimson blossoms of *Cyclamen Coum* give us some brighter hues than we get among the *Crocuses* or the *Snowdrops*. Yet even without these there are bright colours given by the *Primroses* and the *Polyanthuses*, which all winter, so far as it has gone, have never ceased to bloom.

Now, too, is there more variety among the *Crocuses*. Here and there among the clumps of the Dutch varieties some precocious or presuming flower has lifted its head above its neighbours and is ready to open. *Crocus Imperati*, too, which quickly responds to the glances of the sun, has been only awaiting a favourable time to open its purple flowers to lure the bees to enter their cups. To-day the welcome sunshine has come. No prettier *Crocus* have we in January than this, and many would be wise were they to purchase it at the proper season—early autumn—and to plant in generous clumps. It is comparatively a cheap *Crocus*, and thus within the reach of nearly all who love a garden. It seeds freely in my garden, and seedlings are becoming numerous. These give some interest when they flower for the first time, giving always the hope of something distinct from, or better than, the old. This *Crocus* varies more than many are aware of in size of flower and depth of colouring, as well as in time of coming into bloom. The variation in the outer colouring is also considerable, some being entirely free from markings on the fawn-coloured exterior of the segments.

Pretty also, and early flowering, are the varieties of *Crocus chrysanthus*. Two of those I have were kindly sent me from Trinity College Gardens in Dublin. As they open early in the year and, though small, are bright withal, they are admired for their merits alone; the pleasure increased, too, by the thought of whence and from whom they came. These varieties are *C. c. fusco-tinctus* and *C. c. fusco-lineatus*. The former is, as the name indicates, tinted or, perhaps better, "clouded" with brown on a yellow ground on the outside of the exterior segments. The latter is similar, but lined with brown instead of being clouded. For the first time with me another variety, named *C. chrysanthus albidus*, has come into bloom. Like the foregoing, it is small in size, but its colouring is quite different. It is a creamy white outside with a purple base, the interior being white with a yellow zone. It is a pretty little variety worthy of a place in the collection of choice hardy bulbous plants.

Near by is a good clump of the favourite little *Crocus Sieberi*. As this is written it has not yet opened for the season, but its closed flowers are gay with their bright purple points, and when the sun comes again will be very beautiful, covering the corner with a little mass of small, gay purple flowers. There are many other *Crocus* species and their varieties beginning to show colour, and soon there will be a number in bloom. Would that more knew their beauty! A garden which possesses them is a veritable "casquet of gems"—a casquet of precious things more pleasure-giving than any diamond or ruby could be.

The *Snowflake*, too, which, as we have said, has come to contest the place of the *Snowdrop*, merits more than a passing word, inasmuch as a sentence or two may lead to its being added to the favourites of some garden lover. It is not the ordinary *Leucojum vernum*, which comes into bloom later, but the one known to some bulb dealers as *L. carpathicum*. If Mr. Baker is right, it is a yellow spotted *Snowflake*, and I am content to accept his view, although it has been contested. However this may be, the principal use of the name to many will be by its means to be certain of securing the plant desired.

The yellow spotted *Snowflake* is very beautiful as well, but it comes later than the one now referred to. This has large flowers, pure white, with a dark but bright green spot on the exterior of each petal, and two or more blooms are produced on one stem. It appears to be *L. vernum* var. *Vagneri*, of Mr. Baker's handbook of the genus. The flowers of the Spring *Snowflake*, if less graceful and elegant than those of the *Snowdrop*, are very beautiful indeed. Of the *Snowdrops* one may say a word as well. They have come on very quickly, and now many varieties are in bloom. Among those in flower there is the very beautiful *Galanthus Imperati* var. *Atkinsi*, which should be sought after by those who wish to have one of the finest of the *Snowdrops*. Robust in growth, with large and beautifully formed flowers, it is one likely to please the most fastidious.

Among the earliest has also been Mr. James Allen's "Aurora," a flower of perfect form and purity of colour. *G. Elwesii* var. *unguiculatus* is also a comparatively early one, and some of the clumps are now well in flower. *G. flavescens*—the more robust and more deeply coloured of the "yellow" *Snowdrops*—is also in bloom, and is generally well observed, though the "yellow" is confined to the ovary and the markings, generally green in the flower. It is brighter and more pleasing than those who have not seen it may think.

If we look at the base of one of the rockeries we shall find the little azure *Hyacinth* known now as *H. ciliatus*, but more familiar to us as *H. azureus* or *Muscari azureum*. It is botanically a *Hyacinth*,

but to the gardener it is a *Muscari*, resembling the latter in its dense spike of flowers. It is a trifle delicate in some gardens, but suffers in my garden more than anything else from water lodging at the base of the flower stem during rains in January and from subsequent frost injuring the stem. Protection from slugs needs also to be attended to. It is a pretty little plant with its azure blue flowers and its fresh green leaves. There are one or two varieties of this, but none of these has as yet come into bloom.

Anemone blanda is open. It has been in bud for some time, but has at last ventured to spread its flowers to the wind. Had the sun not delayed so long we might have had it earlier; nay, even these *Poppy Windflowers*, which are now in bud, might have favoured us with a peep at their bright flowers. All around are *Daffodils* springing into life. Two days ago it seemed a moot question whether the quaint little *Narcissus minimus*, *N. pallidus præcox*, *N. Henry Irving*, or the *Saragossa Daffodil* would be the first to bloom.

To-day one can almost say with confidence that the tiny *minimus* will be the herald of the *Daffodil* host. Welcome will be its pigmy flowers; welcome in themselves, but thrice welcome as the forerunners of the train of beauties yet to come.—S. ARNOTT.

EARLY AND SUCCESSIONAL CAULIFLOWERS.

COMPACT heads of Cauliflower are largely in demand in nearly all private gardens throughout the summer and early autumn months. From the time they are in season till Broccoli are ready to succeed them it is never safe to let the supply run short; when, however, such a calamity does happen to occur the best course seems to be to prevent the autocrat of the kitchen from knowing the real state of affairs. A little innocent deception of this kind is often the means of helping "life's waters" to run smoothly on instead of being ruffled by stormy waves.

To be able to cut nice heads of Cauliflower during the last week in May or early in June a considerable amount of attention is necessary, and after the plants are set in their permanent positions, if they are left unprotected in severe weather, a serious check, if not total destruction, is the result; but as the crop is always a welcome one it is worth taking a few risks to secure. The old adage about the unwisdom of placing "all our eggs in one basket" is particularly applicable in this case. The safe plan to adopt is to have many successional batches. Now let us suppose we have a good stock of plants, raised from seed sown in August last, and kept in rough pits up to the present time, shutters or other means of protection having been given during the few frosty nights we have experienced during the autumn and winter. Such plants are this year wonderfully forward, as a steady growth has been made throughout the winter. The consequence is they require thinning out at a much earlier date than usual to prevent their receiving a check, which we all know must be avoided if good results are to follow.

In warm districts some of these should be planted out in sheltered positions as early as the second week in February if the soil is in the right condition and the weather favourable. They ought not, however, to be left entirely unprotected. If a few Spruce branches are stuck in the ground so as to shelter each plant on the north and east sides, and left there for a few weeks, the crop will often come through safely, and prove of great service. The plants left in the frames will then in the meantime benefit by the extra room, and early in March an additional quarter can be planted with them, still reserving a few for a third planting a few weeks later. When one has a stock of autumn-sown plants to depend upon, the beginning of February is quite soon enough to sow the small early varieties. The seeds come up quickly then, are sturdy, and grow steadily on as the sun gains power. I like to sow in gentle heat about that time, and as soon as the plants can be easily handled prick them out in boxes.

The advice, "don't sow thickly," is certainly somewhat hackneyed, but is just as necessary as ever it was, for millions of plants are annually ruined through the non-observance of this well known point.

When the young seedlings touch each other as they come through the soil the stems are always weakened and drawn before the plants can be transplanted. In February the majority of gardens are well supplied with pits and frames filled with fermenting materials; these are just the places in which to stand boxes containing newly pricked out Cauliflower plants. After a few weeks' sojourn in such positions they are ready for hardening off preparatory to being set in their permanent positions on a warm border. In severe weather, however, it is sometimes necessary to form rough pits with a few boards to keep the young plants in till warmer weather prevails. A couple of weeks after the sowing has been made in heat, if the weather is favourable, it is advisable to make another sowing in a warm border in the open air; plants resulting therefrom come on steadily in favourable seasons and form a good succession.

For these early sowings there are two varieties which stand out

clearly in advance of others—one is Veitch's Extra Early Forcing, which produces compact heads of snowy whiteness, the other Sutton's First Crop; the latter is a very compact grower, producing white heads and but few leaves. There is not much to choose between the two varieties just named in point of earliness. When these early varieties are sown a little seed of Magnum Bonum, Veitch's Pearl, and Walcheren, should also be put in, because, as they take longer to reach maturity, although sown at the same time, they supply the much-to-be-desired succession. About the second week in March, Autumn Giant or Daniel's King should be sown to supply heads for cutting in August, and by the first week in April another sowing of the same varieties may be made for containing the supply during the autumn. Eclipse is an excellent variety to sow for the same purpose.

When making sowings in the open air it is important to remember that the soil must be dry and in a well pulverised condition. There is not much difficulty in this respect when we are dealing with light soils, but in the case of heavy ones it is often a troublesome business. The small amount of space required for a seed bed, however, makes it quite easy to have a little burnt soil ready for placing in the drills to sow the seeds upon and cover with after sowing. Wood ashes are also of great value for the same purpose, and a supply should always be kept in a dry place ready for operations in spring. All young plants make rapid progress in materials of the above description, not only because they are in the right mechanical condition, but also because they supply food in a concentrated form and in a state suitable for the plants to take up at once. The surface of the seed bed should be levelled with the rake, but not patted with the back of a spade, unless the object of the cultivator is to have the soil cracking in all directions in dry weather, thus allowing the moisture to escape.

Few vegetables require so rich a soil to grow them to perfection as do Cauliflowers; the quarters set apart for them should be thoroughly manured and deeply dug. In planting, the practice of drawing drills about 3 inches in depth is a good one when the soil works well, but on heavy land it is often not practicable. The small early varieties, such as Sutton's First Crop, may be planted from a foot to 15 inches apart, while the stronger growers, such as Autumn Giant, should have a space of 2 feet allowed between the plants.—H. D.

INSIDE v. OUTSIDE VINE BORDERS.

THIS is a subject which in the "days of long ago" has often served as a text to bring into activity the rusty pens of sometimes ready writers, who for a time had laid aside the pen to ruminate upon the erratic behaviour of Vines under their charge. I have often been instructed, amused, and puzzled in turn with those wordy battles of the "scribes of old," who seemed to fight, like Englishmen, to the last, each being determined to vanquish the other.

When the smoke of battle had cleared away, and on-lookers attempted to find out which side had the advantage, they found themselves face to face with a well-nigh impossible task, and the practical result seems to have been the adoption of a compromise in the shape of borders made partly inside and partly out; the front walls of new vineries being built on arches to suit the requirements of that "divided style" of border making. I am well aware that in many instances innumerable grand Grapes have been produced on Vines growing in these "double borders," but I have always considered the principle must be wrong, and especially in the case of early forced Vines—as the temperature of the inside border is often considerably higher than that of the outside one, especially during the winter and early spring months. In our treatment of vegetation of all other descriptions we generally try, as far as possible, to maintain something approaching uniformity of temperature between the surroundings of roots and branches; why, then, should we well-nigh ignore the point in the case of Vines? Is it not one of those inconsistencies that "no fellow can understand?"

I quite expect that someone will be ready to advance a scientific reason for the apparent inconsistency, and I trust they will welcome the opportunity now afforded of illumining the path of us plodding workers with the piercing rays of scientific light. It may be a hard "nut to crack," but it will certainly repay the cracker. We want to know as far as possible the exact conditions under which the roots of Vines can perform their functions so as to produce the best results. It seems to me that a frequent mistake made in regard to Vine borders is to construct them all on the same principle without paying regard to various circumstances which should also be considered. I am no believer in the plan of making half the border inside and the other half outside for the same set of Vines, although I have had to deal with many constructed on that principle.

To my mind there are conditions under which a border entirely inside possesses the greatest number of advantages, while in other instances the outside one perfectly fulfils its requirements; but for the

half-and-half policy I can see no justification. I should never think of making other than an inside border for Vines intended for early forcing, because common sense, as well as experience, shows me that it is the simplest of all methods of keeping both roots and branches at an equal temperature, or nearly so, throughout the most trying season. A large amount of root run is not required, and both roots and branches are then under perfect control. My firm conviction is that half the apparently mysterious checks which early forced Vines seem to get in so many places are caused by the strange practice of having the borders outside the house.

When we come to consider the matter in regard to Vines grown for the production of late Grapes, we have a totally different combination of circumstances to consider. Such Vines are not usually started till March; the sun has by then gained considerable power, and as no great amount of fire heat is employed to start the Vines, outside borders answer well in regard to supplying favourable conditions for the roots during the growing season. The question of keeping the Grapes when they are ripe has, however, to be considered, and it is generally admitted that late Grapes hanging on Vines which have their roots in inside borders keep better than do those on Vines having their roots outside the vinery. This, however, is a matter which has, perhaps, not often been fairly tested, because, of course, heavy rains falling upon the border when the Grapes were ripe in the autumn, would naturally cause the berries to decay; but if wooden shutters were placed upon such borders in September, or early October, if the season were a fine one, I see no reason why the Grapes should not keep as well as those on Vines whose roots were rambling in inside borders.

In the event of very sharp frosts, it would, of course, be necessary to cover the border with other materials to keep frost from the roots. As the Vines would have entered upon what should be their natural season of rest, the lower the temperature of the border—as long as actual frost was kept out—the better for the Vines, and the more likely would the Grapes be to keep in a plump condition. I am quite of opinion that there is a good deal more to be said in favour of outside borders for late Grapes than many cultivators seem to imagine. Where vineries are built in blocks, on the market principle, of course outside borders are out of the question, and this may, perhaps, have had something to do with the almost universal rule of making borders inside for late Grapes in private gardens, where the same conditions do not apply.

I am distinctly in favour of outside borders for Vines grown to produce a crop at midseason, as the necessary warmth is supplied to the soil by the sun, and as the Grapes are not intended for keeping there is no danger of getting a well-made border too wet when a heavy rainfall is experienced. The advantages are that the soil is always kept sweet and aerated by the action of sun and air throughout the year, and this state of affairs is—as all cultivators know—conducive to a vigorous root-action. The cultural operations connected with the dressing and watering of such borders can also be carried out more easily than when the borders are inside. Another serious drawback to inside borders in private gardens is, that as it is generally necessary to grow large quantities of plants in vineries, the borders often become sodden at some point, when they may be quite dry at others; this makes it extremely difficult to know when to water them, as appearances are often deceptive. Then, in addition to the above, the plants growing in the house prevent the sun and air from playing fully upon the border, and in my mind there is no doubt that to secure the best results a Vine border should be devoted entirely to Vine roots. The outside border allows us to do this, and yet turn the house to profitable account by growing plants under the Vines.

There are two sides—sometimes many—to every method of culture advanced, but I fancy the tendency of many Vine growers of the present day has been to entirely ignore the advantages of outside borders; but after many years' experience with Vines growing under a variety of circumstances I have noticed that midseason Grapes invariably colour splendidly when the Vine roots are outside.—VITIS.

AS OF A DREAM.

YOU expressed sympathy with me in 1893 in regard to the two small hybrid Potatoes which I raised by fertilising the Mexican species *Solanum Fendleri* with pollen from my *S. tuberosum* seedling, Antagonist. I have frequently been questioned before and since then by others—those who can feel no farther than their breeches pocket—as to their being "money in it"—not in the pocket, but the seedlings obtained. These questions strike home. Generally I make reply, I cannot ride post to secure patents for my Potatoes; once they become cast upon commerce they belong to the public so far as I am concerned. If they were pinions, say, broken from the wheels of a watch, I could sit down and adjust new pinions at once, and command "money in it" for myself; or in the event of creating an instrument for the destruction of my species I could get it patented at once for my personal benefit. But in the cases of Nature's workings I have probably to wait for years before the good old Dame would enable me to answer the question in the affirmative. (My heaven will

never be looked forward to in connection with "money in it.") I have two curious coincidences, however, agreeably for my theme, which I will unfold for you.

Seventy-two years ago Stevenson caused his first steam-engine to run upon the first railway—Stockton and Darlington. I remember people who shook their heads at that time with but scant appreciation of there being "money in it." My uncle occupied a roadside inn at Sicklesmere in Suffolk. He was a retired stage coachman, and then as now "birds of a feather flocked together." According to them all the horses in the country were to be "thrown out of collar," all the coaches and all the coachmen, ostlers and helpers, were to vanish, and after them—"the deluge!"

Good old prognosticators! they have all travelled to their last bourne—at least, I should think so—if not, whoever of them are left will have seen from the small beginning the wonderful enterprise which now extends to every part of the globe, and to see there is "money in it." Particularly, too, in 1826, and within a few months after the trial of the Stevenson's steam railway engine to impress it for my memory—I was then nine years of age—myself and a younger brother was set by my uncle to pick up a pane of Potatoes in his garden—a very good garden, which John Fenn was very proud and fond of—the recompense for us youngsters to be a treat to Bury St. Edmunds pleasure fair. No Potatoes were ever gathered up by two boys quicker than those "early Shaws" in my uncle's garden, and from that time I date my interest in the esculent. Far be it from me, though, to push myself forward in a "bumptious" manner; but during the intervening years till now, wherever I may have been, the work on my part has been to improve and create largely towards the industrial enterprise and extension of a large commercial trade in a chief and indispensable national food, the *Solanum tuberosum*.

Allow me also to ask: From 1857, when the providential inspiration came to me in the old rectory garden at Woodstock anent the artificial cross fertilisation of the Potato, has there been any other aliment for food that has taken such a leap and bound? I have just been reading our Secretary for the Colonies speech at Liverpool. Mr. Chamberlain said, "One great principle is that every country should produce and should be encouraged and allowed and stimulated to produce articles for which by nature it is best fitted." Allow me to say that the Potato is one of our best permanent pabulums of food, and the supply should be quadrupled by cultivation in our English soil for which it is "fitted." As I am led to infer from Mr. Chamberlain's speech, aid is likely to be offered to our West Indies to grow their sugar, why not to us at home? Government money, say at about 2 per cent., in aid to grow Potatoes, Wheat, or anything else to work back our land into good husbandry and value, enabling us so much the more to depend upon ourselves to feed our millions all the more securely. There would "be money in it," directly and indirectly sustenance for stamina, for there is no produce in the world to equal the British for "sticking to the ribs."

I have read how the State of Denmark voted £100 in 1896 for "carrying on certain experiments" *re* the making of butter. I heartily wished our Government would help the British agriculturist after a like manner; the sort of aid and encouragement expressed would tend for us to produce British butter in much larger quantity and better than Denmark or any other State could send us. I fancy you have partaken of good butter at my cottage farm, made in Berkshire. But then I read and study the "Home Farm" articles published weekly in this "our Journal." The advice they afford us in our independent lines of action would be found hard to beat. But the cat appears to be jumping in the way you may read between the lines, of me "Colin Clout, as I go about, and up and down I walk and hear the people talk." But I have only just room here to say, that soon after you had seen my two little Fendleri seedlings, which began this "dream," I planted them in a reversed Seakale pot, to stand upon the soil of my seedling Potato trough in the glass house; so, at any rate, what I have said I hope you will think to be sufficiently interesting to have "whiled away the time," whilst the hybrids grow into details for my next paper.—ROBT. FENN.

[The history, accidents, and troubles attending the raising of the hybrids are detailed on page 3, January 5th, 1893, vol. xxvi., of the *Journal of Horticulture*. It was a bad beginning—the precursor, we will hope, of a good ending. Mrs. Fenn's butter is good. We say nothing about the "2 per cent." yearnings of her "Colin."]

BALL DECORATIONS AT CIRENCESTER.

I THINK a line *re* the arrangements of the supper tables at balls held on January 26th and 28th might interest the readers of the Journal. They struck me as being of an unusual character. I suppose there is no name better known as an exhibitor at all the leading summer shows than that of Mr. Jas. Cypher, and certainly not one more successful, and he appears to be equally as capable as a decorator of supper rooms.

On the present occasion the centre table was of diamond shape, on the centre of which was a pedestal surmounted by a Kentia, whose fronds drooped gracefully, forming quite a picture of itself. From the base of the pedestal to each corner of the table an arch was placed, forming a series of arcades, and from these were suspended flowers and foliage, such as Asparagus, various kinds of suitable Ferns, *Ficus repens*, Orchids, Lilies of the Valley, Anthuriums, Narcissus, and such like flowers. Between these arches were disposed elegant specimen glasses of the choicest flowers—of course, Orchids playing an important part.

On each of the other tables (which were round ones) was placed an

elegantly arranged basket, in the centre of which was a perfect little *Cocos Weddeliana* surrounded by choice flowers. Everything evinced the greatest taste and skill. I was too late, or I should probably have sent you a photo of the room, as I am sure it would have given pleasure to you.—T. A.

PEAR PRESIDENT BARABÉ.

ON our reporter going to the side table in the Westminster Drill Hall, on the 11th ult., to take a description of this Pear for publication, he found nothing but stalks. After products are removed from the Committee table they are arranged for inspection by the public, and no one is entitled to interfere with them. Even the judges of fruit in the dessert classes are only empowered to cut a stipulated number, and must leave the remainder intact. The gentleman, however, who discovered a Pear which gratified his palate is evidently generous hearted, for he invited a friend to share the feast, and they may now be interested to learn that a lynx-eyed pressman (not of this Journal) watched the connoisseurs, as he says, "clear the dish." This is mentioned for two reasons. (1) To remind our friends (who are very well known) that in a moment of

FIG. 15.—PEAR PRESIDENT BARABÉ.

forgetfulness they did not set a good example; (2) because they bore very practical testimony to the excellence of President Barabé Pear.

As good midwinter Pears are not over-plentiful, and as it is somewhat rare for a first-class certificate to be awarded for one at the beginning of the year, Mr. W. Allan of Gunton Park, the exhibitor on the occasion, obliged by sending us a couple of fruits, one of which is represented in fig. 15. The largest gathered weighed from 7 to 8 ozs. Our description of the Pear examined is as follows:—

Fruit, medium sized, 2½ inches wide and nearly the same in height; uniform, obovate; skin, lemon yellow, almost entirely covered with brown russet on one side, and rather heavily mottled with yellow and russet on the other; eye, very large with erect woody segments, set nearly level with the surface and surrounded by a clear lemon (*i.e.*, free from russet) ring; stalk, ½ inch long, stoutish, thickening towards the end, slightly oblique and set in a small shallow cavity; flesh, yellowish white, with a distinct yellow band next the rind, slightly coarse in the grain, yet at the same time not devoid of a buttery texture, sweet, juicy, but slightly sub-acid, imparting a rosewater flavour, pleasant and refreshing. President Barabé is a welcome addition to December and January Pears. It is of French origin, and was, we think, introduced by Messrs. James Veitch & Sons, Ltd., who describe the tree as hardy and very prolific, forming good cordons or pyramids on the Quince stock.

Mr. W. Allan says that President Barabé on the Quince stock is grown on a south wall in Gunton Park Gardens, Norwich, the tree being vigorous and very prolific. He remarks that the fruit two seasons out of three requires thinning to avoid overcropping. In his district it is distinctly a January Pear. Mr. Allan continues, "This late Pear ripening so well here, and proving so excellent in flavour, augurs well for its success in warmer counties, as some of the well-known late varieties, like *Nec Plus Meuris*, do not ripen well here, even on south walls."

GREENHOUSE AND CONSERVATORY FLOWERING SHRUBS.

TEN MINUTES' NOTES.

THE older fashioned of these seem to be conspicuous by their absence nowadays. It is my intention to name a few, with concise cultural notes, that flourished so well under the treatment given them by Mr. Channing in the conservatory at Lillesden, Hawkhurst, Kent, where some years ago I was foreman.

LUCULIA GRATISSIMA.

This was a great favourite, planted against a shady wall in a compost of peat, loam, leaf soil, and sharp sand. It grew luxuriantly, and in early winter was clothed with its flesh coloured, fragrant flowers. The roots were confined, and the border well drained. During the growing season this plant needs abundance of water, with daily syringings, withholding as soon as the flower buds are seen until such time as it starts in growth again. The waterings in the intermediate space must be guided by the absolute requirements of the plant only. Pruning is not imperative where space is unlimited. The dead flowers and irregular shoots may be removed, and the remainder tied in their places; or it can be spurred back in February if preferred. Propagation is achieved by cuttings taken with a heel when the young growths are 3 or 4 inches long, inserting without delay in previously prepared pots with plenty of sharp sand, placing them in a close propagating pit, and preventing flagging by occasional dewings. When rooted the hardening process must be very gradual.

HABROTHAMNUS (CESTRUM) ELEGANS.

An old favourite under a new name. This plant is good for walls, pillars, or roofs. Under the planted-out system and with liberal treatment it may be said to be always in flower; an open moderately rich soil, with plenty of water during the summer months, are its requirements. Do not allow the growths to get too crowded, and you will be able to cut armfuls of its dull red flowers. An occasional dose of liquid manure assists plants of weak growth. Cuttings root freely under ordinary treatment. It makes a suitable amateur's plant, as it is not fastidious as regards temperature, soil, or position. Occasionally green fly is troublesome, especially in the flowers; fumigation will clear them, with good syringings afterwards. Mealy bug, too, takes a liking to this plant: when the attack is very bad a radical cure is to cut the plant hard back, burn all refuse, and paint the pillar or rafter well with paraffin.

LONICERA SEMPERVIRENS.

A beautiful evergreen climber is this, flowering nearly all the year round, though naturally more profusely in spring. When pruning always remember it flowers on the young wood. Its beautiful scarlet and yellow flowers are produced in whorls. Partial shade seems to suit it better than too much sun. Ordinary light fertile soil suits its requirements. Given this, and in a cool greenhouse, with plenty of head room, it is a most desirable plant to grow. It is easily raised from cuttings, or root division where practicable. Late pruning will retard the flowering season.

PLEROMA MACRANTHA, SYN. LASIANDRA.

One so rarely sees a blue flower in winter, or perhaps I should be more correct in this instance in saying bluish purple, which this plant produces, that the wonder is it is not more generally grown. It was planted out, and covered nearly all the gable end of the conservatory, where it flowered splendidly all the winter, the dark glossy leaves forming a beautiful contrast to the many large flowers. A compost of two parts loam with one each of peat, leaf soil, and a sprinkling of sharp sand, may be recommended. This plant succeeds best at the warmer end of a conservatory, and needs copious supplies of water during the growing season, and such rest as "A.D." (page 553, last vol.) advocates, at the proper season. The flowers will not last when cut, but their sight on the plant is ample compensation.

CHOROZEMAS.

I fancy the varieties we grew on balloon trellis and also as climbers at Lillesden must have been *C. Chandleri* and *C. cordatum splendens*. The plants in pots used to be treated somewhat like Heaths. A compost, with peat predominating, was used. After flowering the pot plants were stood under the shade of a tree, the pots turned on their sides during heavy rains, and taken indoors in the autumn. As soon as growth commenced the plants were cropped close with a pair of shears. Careful watering is needed at this stage. The pillar plant was treated alternately with rest and growth annually, and in its season was a "thing of beauty." Thrips were troublesome at times.

SPARMANNIA AFRICANA.

These were grown in large pots, and well repaid for generous treatment. As the spring advanced and the season of flowering exhausted they were cut hard back, a little of the surface soil removed, and top-dressed with rich compost, then placed on ashes outside in the full sun, reducing water until growth was on the move. No more than ordinary attention is needed, except giving the plants the benefit of a little weak liquid manure occasionally. As autumnal weather comes along wash the pots, examine the drainage, and remove to winter quarters. Strong shoots should be produced, and bristling under the leaves will be found buds in all stages, which the genial warmth of the conservatory soon develops into a galaxy of curious white flowers, surmounted by

yellow powdery stamens, which remain erect after the petals fall. It is readily propagated by cuttings in heat.

OTHER PLANTS.

Other plants well grown there were *Lapageria alba* and *rosea*, *Bougainvillea glabra* (which flowered splendidly), *Stigmaphyllon ciliatum*, *Bignonia venusta*, *Jasminum grandiflorum*, *Mandevilla suaveolens*, *Plumbago capensis*, *Tecoma jasminoides*, *Boussingaultia baselloides*, *Thea viridis*, *Clematis* in variety, and last, but not least, were the splendid *Camellias*, which, after receiving good support and copious waterings and syringings during the growing season, paid back a thousandfold with gorgeous masses of flowers, to brighten the dull days of winter.—GEO. DYKE, *Stubton Gardens, Newark*.

THE VANISHING CORN FIELDS.

I HAVE to thank "A. C." for his flattering remarks (page 81) concerning the literary merit of "A Dream of the Future," and I am not surprised that he should have described the sentence he singled out as a startling one. There can be no doubt that the small quantity of corn grown in this country creates a state of affairs which may at any moment be turned into a grave national danger unless steps are taken to provide against contingencies. Let us admit that at the present time there are thousands of acres of land in Britain now laying idle which ought to be turned to account for Wheat growing. Then surely something could be done to enable farmers to grow Wheat at a slight profit, and thus make our danger less for a time, although we could not grow enough to provide a full supply for our teeming population.

This, however, could only be a temporary arrangement, because with a population increasing so rapidly we should each year produce a smaller proportion of the Wheat required. Perishable crops, such as vegetables, fruit, and herbage for cattle, would have to be more largely grown each year, till in time, though perhaps at a very distant date, the whole of the available land in Britain would be required for these purposes. Then what about our supply of corn? Fortunately grain has one advantage—viz., that it can be stored for several years without seriously deteriorating in quality. It is thus easy to see that as this little island becomes more closely packed with human beings, Wheat is the one necessity of life which can be most easily be "stored" ready for the dark hour of need.

It seems to me, therefore, that those who guide the helm of State in the future will be forced to consider it their imperative duty to store up a few years' supply of corn regularly, and that such a duty is second only in importance to that of maintaining British supremacy upon the "ocean wave." This may not appear to many the right way to march "onward," because in a modified form, and for different reasons, the practice of storing grain was started in the "land of Pharaohs" long ages ago, when Joseph was brought from the dungeon to interpret his monarch's dream. Still, it has become a firm conviction with—ONWARD.

BEST FLAVOURED PEARS.

AMONG varieties which rank high in flavour, only a limited number seems generally known, as correspondence on the subject in your paper shows gaps in the supplies. This ought not to be so, as really good varieties exist, and might be expected to appear on such opportunities as are offered by the Veitch prizes for flavour at the Drill Hall meetings, but where only one or two dishes figured on the last occasion.

Glou Morceau, named by Mr. G. Dyke, is doubtless a fine Pear in its season, but it requires favourable southern conditions on walls, or espaliers and bushes, as in walled enclosures, or where other good shelter is afforded. In comparison with *Beurré Rance* and *Bergamotte Esperen*, I have found *Marie Benoist*, *Olivier des Serres*, *Prince Napoleon*, and *Doyenné d'Alençon* preferable, and as they are in season from January to March their appearance at the Drill Hall would not be otherwise than opportune. I have grown them for fifteen years, and thus write from experience.

The new variety *Le Lectier* should also be included, for being in season in January and February, as well as *President Barabé*, newly introduced at the Drill Hall, and found to be a first-rate midwinter Pear, I think it cannot be too highly praised, and reminds me of Thomson's, a superior October and November Pear that should be on every garden wall with a southern aspect, together with *Beurré Bosc*. For *Nec Plus Meuris* I have a good word to say, as grown in bush form.

The younger branches of a family alluded to by your correspondent would doubtless be delighted to have Pears earlier than are provided by *Seckle*, which with me is all honey and water, and I should recommend bushes of *Citron des Carmes* and *Doyenné d'Été* to eat from the tree in July and August respectively, with *Jargonelle* and *Brookworth Park* to follow. The somewhat later best sorts not mentioned by Mr. Dyke are *Madame Treyve*, *Louise Bonne de Jersey*, *Beurré Hardy*, and *Emile d'Heyst*, while if very large Pears are appreciated *Souvenir du Congrès*, *Beurré Diel*, with the December Pear *Nouvelle Fulvie* (on a south wall) should be added. In appearance, *Marguerite Marillac*, an October Pear, cannot be beaten, as seen at the Crystal Palace Fruit Show.—H. H. R., *Forest Hill*.

WEATHER IN LONDON.—The mild weather which has characterised the weather for several weeks still remains. Last Thursday, Friday, and Saturday were cool in the evening, and rain fell slightly on the latter day. Sunday morning brought heavy showers, but Monday was a magnificent day. Rain fell during the early hours of Tuesday morning, and the day was dull throughout. Wednesday was fine, but not very bright.

WEATHER IN THE NORTH.—Westerly winds have prevailed during the past week, and the weather, while variable, has been generally fine, with high temperature both day and night. Friday was particularly fine. On the nights of Sunday and Monday a good deal of rain fell. Tuesday morning was clear and somewhat colder.—B. D., *S. Perthshire*.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Royal Horticultural Society will be held on Tuesday, February 8th, in the Drill Hall, James Street, Westminster, 1 to 4 P.M. At three o'clock the annual general meeting of the Society will be held in the Lindley Library, 117, Victoria Street, S.W. The Committees will meet as usual.

DEVON AND EXETER GARDENERS' ASSOCIATION.—At the last fortnightly meeting of this Gardeners' Association, the essayist for the evening being Mr. George Lee, gardener to Miss Lavers, Upton Leigh, Torquay. Mr. W. Rowland, gardener to Mr. W. Brock, was in the chair. Mr. Lee, who is a specialist in Orchid culture, traced the history of the Orchid mania from the time that Swainson explored the Brazilian forests, life in hand, extricating plants from malarious swamps alive with lizards, alligators, and other dangerous beasts of prey, sent home to England the Cattleyas, with their gorgeous hues and majestic forms. The essayist also gave exhaustive cultural details, which were most interesting.

STRAWBERRIES FROM SEED, OR THE CULTIVATION OF THE ALPINE STRAWBERRY.—This was the subject of a paper read by Mr. James Hudson of Gunnersbury, before the members of the Reading Gardeners' Association, last week, when Mr. C. B. Stevens presided over a good attendance of members. The subject was certainly a new one, and perhaps the first time that a paper on this particular fruit has been given before a gardeners' association. In the discussion which followed all the members taking part had to plead ignorance of the cultivation of the Alpine Strawberry, but many of the gardeners will no doubt be giving it a trial. A hearty vote of thanks was accorded Mr. Hudson for his interesting paper. A box containing some 120 to 140 spikes of well grown Lily of the Valley, many having fourteen and fifteen bells each, was shown by Messrs. Rigg & Fixter, Caversham, and attracted great attention.

THE CAPE COLONY AND GARDENERS.—One of the best authorities in the above Colony having been written to on subjects which are indicated has favoured with the following reply:—"Your letter, dated November 19th, to hand. Let me assure you it affords me great pleasure to give you or any gardener in the old country such information as may be of use. I have now been in South Africa for seventeen years, during which time I have been in the Transvaal, Orange Free State, and in all the larger towns in the Cape Colony. South Africa is the last place I would recommend any gardener to come to look for work. The few gardeners that are in charge of parks or botanic gardens in the different towns command salaries from £250 to £350 per annum. There are very few openings. In Johannesburg there are hundreds of gardeners who cannot get work at their trade, and those who do have to work for about 5s. per day, which is nothing like a living wage in that part, as you cannot get a cottage to live in for less than £10 per month. As a seed-growing country I think it would be far before anything in Europe. If anyone had sufficient capital and had certain sale for seeds I think a fortune could be made. I should say Balsams seed more freely here than anywhere, and Dahlias are also very free to seed, as are innumerable other things, including vegetables. There are occasional droughts, which have been very severe this year, but these are not like the poor, "always with us." For a seed farm great care would be exercised in choosing a suitable spot, and a good capital would be essential, as many persons have ruined themselves at nursery work, just from want of sufficient means. On any other terms I would not advise any gardener to come out here, especially a married man."

GARDENING APPOINTMENT.—Mr. W. Heath, head gardener at Woodland's Vale, Ryde, Isle of Wight, has been appointed to a similar position at Wokefield Park, Berks.

ROYAL BOTANIC SOCIETY.—At the last meeting of the Fellows of the Royal Botanic Society held in the museum at the Society's gardens, Regent's Park, Mr. C. E. Layton presided, and there was an unusually large attendance. Four new Fellows were elected, and nine were nominated for election at the next meeting. Professor Henslow read a paper on "Plant Variations," which he illustrated by means of a large number of photographs reflected upon a screen.

MR. W. HOWARD.—The following has been forwarded to us from a Kingston paper:—"Mr. W. Howard, the manager at Messrs. Veitch & Sons' Nursery, Kingston Hill, is about to relinquish that appointment. He has been connected with the firm for thirty years, and is highly respected by prominent men in the horticultural world. His knowledge of home and foreign plants is great, and he is looked upon as an authority in the profession. The good wishes of many will follow Mr. Howard into his new sphere of work."

ROMAN HYACINTHS.—I send a photograph of our Roman Hyacinths which number about 500 plants. They were taken out of boxes a fortnight before being photographed, and are still as good as ever. I gave my method of culture in the autumn of 1897, and a brief recapitulation may be of interest to some persons. I place fifty bulbs in a box, of which the dimensions are 2 feet by 1 foot and 3½ inches deep. This is well drained, and a fairly moist compost, consisting of one part loam and the other leaf soil and sand, is used. The bulbs are placed evenly on the surface of the boxes half filled with the compost. I then put the boxes into a stack by placing an empty box, reversed, over every full one in the corner of a rather damp shed. They are left like this till the growths are 2 or 3 inches long, when they are gradually exposed to light till quite green. A gentle heat brings them into flower as wanted.

—R. BASSIL, *Shooters Hill Gardens, Pangbourne*. [Though the photograph is, unfortunately, unsuitable for reproduction, it may easily be seen how successful is the system of culture adopted, and upon the results of which we congratulate our correspondent.]

THE ROYAL FAMILY AND FLOWERS.—The members of the Royal Family confess to a great love for flowers of all kinds. The Queen (according to the "Woman at Home") has a special weakness for Lilies of the Valley and Violets, and cares to have them about her rooms. Her intimate friends, knowing her favourite blossoms, send her these in profusion upon her birthday, at Christmas, and the New Year. Violets, the pet flowers of the late Emperor Frederick of Germany, have become quite sacred in the eyes of his widow, and she has often been deeply touched when, paying her annual visits to England, mere strangers have offered Violets "in remembrance of her beloved husband." The Duchess of York is much interested in the cultivation of flowers. For her own personal adornment she prefers Lilies of the Valley and white Roses. The Princess of Wales, however, is the most ardent enthusiast for flowers, and is never content unless her rooms are simply one mass of scented blossom. In her own boudoir at Marlborough House and at Sandringham, every available table or stand bears a burden of plants in pots, and vases frequently replenished with choice cut flowers; and in the hall at Sandringham the Palms and greenery are a sight to behold. As for the Prince of Wales, he cannot endure to be without his "buttonhole."

THE GARDENERS' BENEVOLENT BALLOT.—As Mr. Outram has drawn attention to the number of lost votes arising from the non-signing of voting papers, permit me to suggest that to render the election a genuine ballot, the Secretary should stamp every voting paper with an impressed stamp of the Institution, and number it legibly in red ink. He should have a list of subscribers in a book, arranged corresponding to the numbers on the ballot paper. In that case signing would be needless. Should the authenticity of any ballot paper be disputed, the scrutineers alone should have power to verify or otherwise when the counting was in progress. No paper should be sent to anyone whose subscriptions due had not been paid. It is monstrously unfair that such persons should be recognised as subscribers at all. This plan, whilst practically rendering improper voting impossible, would be a real ballot, and not as now a sham one. Then no voting papers should be accepted that were not returned at least two clear days before the day of election into the Secretary's hands, and that official should be held responsible for placing them in the hands of the scrutineers just as received when they retire to count the votes. When the counting is proceeding, no person other than the scrutineers should be permitted in the allotted room until the counting is completed.

—A. D.

— A ROSE PUZZLE.—Will any reader of the Journal tell us how to understand the following class for Roses, as copied exactly from the Newcastle-upon-Tyne summer show schedule for 1898:—"Cut flowers.—Class 52, thirty-six Roses, twenty-four dissimilar, in triplets." Would it not have looked more like business if it had been twelve varieties in triplets? which I presume it must infer. Nobody seems to know.—GEO. FINLAY.

— FLAVOUR FROM LEAVES.—M. Jacquemin, a French pharmacist, has invented a process by which he says he can form from the leaves of various fruit-bearing trees and shrubs the flavours that are characteristic of the fruits themselves. From Apple tree leaves, crushed and fermented, he obtains a liquid possessing the fragrance and taste of Apples, and from Vine leaves a beverage resembling wine. His theory is that the peculiar flavour of Apples, Pears, Grapes, and berries is prepared in and derived from the leaves of the plant, and in our opinion this is true.

— THE WOLVERHAMPTON FLORAL FÊTE.—This compares well with similar undertakings in other towns. Last year's show made a profit of £421 10s., the gross takings, £2390 2s. 4d., showing an increase of £87 16s. 9d. on the present year. At the annual meeting of the Committee Mr. S. Dickenson made some gratifying observations on the success of the Fête during the past nine years, mentioning that the total profit in that period had been £3956 18s. 6d., out of which the Committee had built shelters, greenhouses, and paid for music in the public parks, as well as placed to the reserve fund no less than £786 12s. Wolverhampton, therefore, has cause for gratitude to those who promoted, and those who carried on this undertaking,—("Birmingham Daily Argus.")

— LIVERPOOL HORTICULTURAL ASSOCIATION.—On Saturday evening last Mr. Thomas Foster presided at the nineteenth annual general meeting. The Secretary's report, whilst regretting the apathy of the public in supporting the shows, classed the summer show held in Sefton Park and the autumn show in St. George's Hall as amongst the finest held by the Association. The Sub-Treasurer's account showed a loss of £357 13s. 3d. on the two shows, an item which ought not to appear this year if the public at large will only give their valuable support. Subscriptions of 3 and 2 guineas respectively were granted to the Gardeners' Royal Benevolent and the Gardeners' Orphan Funds. The balance in hand is about £80. The Right Hon. the Lord Mayor, Alderman Jno. Houlding, was elected President for the ensuing year; Arthur Crossthwaite, a Vice-President; and Messrs. Jas Bethell, E. Finch, and Geo. Eaton to fill vacancies on the Committee. Messrs. Disley and Dickson were respectively nominated for the secretaryship, each receiving twenty-three votes, the Chairman's casting vote being in favour of Mr. Dickson. A sensible proposal, made by Mr. Hitchman, that the Committee be empowered to fix the show dates before the date of annual meeting, was received with approval. It is proposed to hold a grand spring show in St. George's Hall and the usual popular Chrysanthemum and fruit show. The usual votes of thanks closed the proceedings.—R. P. R.

— THE R.H.S. EXAMINATION.—I observe you have been giving an inquirer some useful advice with respect to this examination. It tallies entirely with my own views. April is not far off, and those who purpose sitting at the next exam should make the best use of their time. Generally the examinations have little value for anyone except those who may be gardeners, or contemplating to become such. Then the grades should be dissociated, having a purely practical one, and a purely theoretical or scientific one, leaving to students option as to which they should enter, but granting no first-class awards until both grades had been well passed. That sort of exam would tend then to show what amount of practical knowledge the college, laboratory, and correspondence crammed candidates possessed. That questions in theory get a higher number of marks than do more important ones for gardeners in practice, seems to be the case. But apart from all the existing defects of the present system, I always strongly advise young gardeners to submit themselves to the examination. If they set themselves earnestly to work to master the desired knowledge, and even then fail to obtain a high number of marks, they will have done themselves immense good. That is a result worth more than any mere pass honours. Shakespeare puts into the mouth of the fallen Wolsey the bitter lament, "Had I but served my God as diligently as I have served my king, He would not in mine age have left me naked to mine enemies." This represents throughout all time the inevitable bitter cry of old age over the follies and wasted opportunities of youth. How many a young gardener of to-day is there fooling away time and opportunity who later in life may not have occasion to re-echo in paraphrase the remorseful cry, all too late, of the fallen Cardinal.—A. D.

— NOTES ON PEARS.—My experience of Beurré Rance in this district for the past five years is identical with Mr. Easter's and Mr. Dyke's—namely, useless for dessert, and I may say the same about Nec Plus Meuris. I have them here on a good south wall in fairly good loam on a sandstone formation, but I have not yet had the pleasure of tasting a good fruit. I have come to the conclusion that it wants a warm atmosphere. Glou Morgeau, Beurré Diel and Louise Bonne of Jersey have done excellently on the same wall and situation.—T. HANSON, Garforth, near Leeds.

— MASSACHUSETTS HORTICULTURAL SOCIETY.—We have received the schedules of the six exhibitions of this Society that are to be held during the year 1898. We observe that at the six shows a total of upwards of 8000 dollars is offered in prizes in 786 classes. These comprise practically all phases of gardening, including those for greenhouses and gardens. The rules for exhibitors are brief and generally straight to the point, and no difficulty should be experienced in interpreting them. The shows will be held in the Horticultural Hall, Boston, as follows:—Spring Show, March 22nd, 23rd, 24th, and 25th; Rhododendron Show, June 2nd and 3rd; Rose and Strawberry Show, June 23rd and 24th; Plant and Flower Show, August 31st and September 1st; Fruit and Vegetable Show, September 29th and 30th; and Chrysanthemum Show, November 8th, 9th, 10th, and 11th. The Secretary of the Society is Mr. Robert Manning.

— HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—A meeting of the above Society was held on Tuesday, January 25th, Mr. Geo. Picker, Hesslewood, in the chair. The essayist for the evening was Mr. H. J. Clayton, Grimston Park Gardens, Tadcaster, and the subject, "Notes on Gardens and Garden Management." The essayist dealt with gardens, first going right back to the Creation—e.g., the Garden of Eden. He then followed with other notable gardens mentioned in history, and finished by describing an ideal garden of the present day. In his notes on the management of gardens he spoke of the advantages probationers derived by serving at least three years in the outside gardens, and pointed out that to grow good vegetables and hardy fruits was equally as hard a matter, and required as much care and forethought, as to cultivate the choicest Orchids. Mr. J. S. Barker showed well-flowered plants of *Lycaste Skinneri* in variety.—G. W. G.

— ROMANCE OF INSECT LIFE.—At the Public Hall, Woking, on Sunday afternoon, Mr. Fred Enock, F.L.S., F.E.S., once a resident of that town, spoke about "The Wonders and Romance of Insect Life." There was a good attendance, and the lecture, which was illustrated by lime-light views of exquisite beauty, was intensely interesting. Mr. Enock first dealt with the green fly. Millions and millions may be found on a single tree, sucking away its life-sap, and incalculable injury would be done by this pest were it not for the check which Nature has provided in the wasp fly. This parasite lays its eggs in the body of the green fly, and the maggot feeds upon the flies, which it destroys at the rate of a hundred or more per hour. Gardeners destroy these maggots, but they are among their best friends, for each one lives a fortnight, and during the whole of that time is destroying the green fly. The maggots may be known by the way they wave their bodies about. The wasp fly, it is interesting to note, has two compound eyes, each containing some 11,000 separate lenses. Then there is the gall mite, only one-four-hundredth of an inch long, which is terribly destructive to Black Currant bushes; but here, also, there is a parasite in the shape of a maggot which eats these tiny grubs. The Willow-tree gall is produced by the saw fly, whose egg-laying apparatus is shaped exactly like a saw. This insect does not saw right through the Willow leaf, but only half way. It then forces its saw between the upper and lower skin of the leaf and lays its egg in the farther extremity. The irritation thus set up—on the same principle as a thorn in our finger—produces the gall, which is the home of the maggot into which the egg changes, and likewise its food, until it is big enough to leave, when it becomes a chrysalis and fly in the ordinary course. But although these galls are so common the fly itself is comparatively scarce, owing to the destruction of its eggs by a parasite. This parasite pierces the gall and kills the grub with a tiny drop of acid, and then lays an egg of its own inside the gall, the grub of which, when hatched, eats all the poisoned grub except its skin, which it utilises as a cocoon, to save itself the trouble of spinning one. The devil's coach-horse beetle is another interesting insect, and has a marked predilection for green caterpillars—or London restaurant caterpillars, as the lecturer prefers to call them. It is therefore useful, and should not be destroyed. The lecturer concluded with an account of some discoveries in the insect world which he had made, and, referring to his three years' residence in Woking, said he believed he was then locally known as "The Madman," because of his fondness for insect hunting.

— **PROTECTING PEARS.**—The protection by cotton bags of growing fruit recommended by "A. D." a few weeks ago would probably interfere too much with the maturity, perfection, and colouring of the fruit. I tried successfully some years ago the use of similar bags, made of cotton in very transparent open net, useful as mosquito netting. It admits plenty of light and air, thoroughly excludes all insects, and repels birds, and I know of nothing better for the purpose. —H. H. R., *Forest Hill*.

— **INDIAN SHADE TREES AND THE COFFEE PLANTATIONS IN NYASALAND.**—A proposal was made some time ago for the introduction of the seeds of certain trees from India and Ceylon into British Central Africa, for the purpose of supplying shade for the Coffee plants in the numerous plantations which are now being opened up in the protectorate. The suggestion was referred home by the Commissioner, and the Foreign Office requested Mr. Thiselton Dyer, the Director of Kew Gardens, to report on the subject. As a result of Mr. Thiselton Dyer's reports, her Majesty's Commissioner has determined rigidly to enforce the regulations for the prevention of Coffee disease in Central Africa, which prohibit the importation of seeds from India and Ceylon. In his report Mr. Thiselton Dyer says:—"The Coffee disease was introduced into Fiji through the instrumentality of Tea seeds from Ceylon. Notwithstanding the splendid attempts made by Sir William MacGregor to stamp it out, it ultimately completely destroyed the Coffee industry, which was the most promising planting enterprise in the colony. The Germans, by some unknown means, have succeeded in introducing the disease into their African territories. In the face of these undoubted facts, it would, in my opinion, be the height of folly to run the smallest risk of introducing the disease into British Central Africa, where its presence would be an irreparable disaster. Knowing the mechanical way in which such work is carried out by native officials in India, I do not think that any stipulation as to locality is of the smallest value. Whatever was stated to the contrary, the first parcel of seed would, in all probability, come from a plantation reeking with disease. The present request is the more unnecessary, as according to a Coffee planter in Nyasaland, who is well acquainted with Coffee cultivation in Ceylon, a local African tree, *Albizia fastigiata*, is admirably adapted for a shade tree for Coffee. If this is not sufficient, the Rain Tree, or *Pithecolobium saman*, might be tried. The seed can be obtained in abundance from Jamaica, and this would be perfectly safe." —("Times.")

— **GARDENS IN ENGLAND AND ITALY.**—At the galleries of the Fine Art Society in New Bond Street may be viewed a new series of water-colour drawings of gardens by Mr. George S. Elgood, who has for so many years enjoyed popularity as an artistic authority on those combined efforts of Nature and the hand of man that go to the making of beautiful gardens. Hitherto Mr. Elgood has loyally chosen as subjects for brush and pencil the gardens of England, but for this occasion he has been working chiefly in a sunnier part of the world. In the gardens of Italy, he reminds us, we are to seek the origin of our more formal phases of horticulture, especially the occasional introduction of statuary sometimes ventured upon by owners of picturesque seats sufficiently distant from the grime of London fog and smoke. At Pompeii were found the roots of the Box borders dear to our grandparents, and at La Cava the square-clipped hedges and topiary work, the prototypes of our seventeenth century gardens. Palermo provided the artist with a little mine of wealth from the pictorial standpoint, both in private and public grounds, where lovely surroundings form a setting for the more conventional results of special design. For the Yew-clipped hedges and elaborately cut devices which still border many a pleasant walk, whose well-swept, tyrannical order repels the lover of wayward picturesqueness, Mr. Elgood has an affection that belongs to historical association. The more formal subjects are clothed in the glamour of Old World peace, while on the other hand there are many in which the studied skill of the gardener is modified by the bold growth of blossoms outgrowing the restrictions of space; and when this happens under artistic direction, the contrast between festooned arches and the patches of free luxuriance has not less but a different sort of charm. Illustrations of this will be found in some of the gardens at home, to which we may return after appreciating the grounds of ancient monasteries, the Lemon groves of Palermo, and the flowers and Olives of Florence. Profuse in beauty is the Rose garden of Newlands, Hampshire, belonging to Colonel Cornwallis West; and a combination of graceful formality and freedom will be seen in several drawings of Great Tangle, where Mr. Wickham Flower helps to keep up the reputation of Surrey for a soil that is so generous to floriculture. Once again, too, Mr. Elgood has painted such famous spots as Hardwick and Easton Park, and the delightful Deanery Garden at Rochester.—("Daily News.")

— **HOEING.**—The gardener will always find abundant success if he will not neglect the use of the hoe. It is wonderful what tillage will bring out of the soil. Most men must till to keep down weeds. They do not realise that the benefits of this work are far above any mere weed killing. By persistent cultivation we get the soil loose and mellow, porous and light, so that air can enter and roots freely branch, and distribute themselves throughout the entire mass of earth within their reach. Furthermore, tillage is a breaking-up process, particles of rock and organic matter being reduced in size and made available for the nutrition of crops. Then there is, says a writer in an American contemporary, the immeasurable effect of shallow surface cultivation in forming a mulch upon the surface of the ground, a thin layer of loose, dry earth to cut off the rise of moisture to the surface, and its subsequent evaporation and loss to the use of the growing plants. Water in a drought is a priceless boon to vegetables, and conserving the supplies of moisture is one of the most vital subjects with which the cultivator has to deal. Tillage is to a certain degree manure, as was claimed by Jethro Tull of old.

— **WATERING HOUSE PLANTS.**—I am satisfied that not one person in twenty is aware that too much water is more dangerous to the plants than too little. Some gardeners seem to have the idea that to take a watering pot in hand to supply the needs of plants is an easy duty, and that to give a dash here and to soak the soil there is all that is needed. One thing is to be observed: All plants under all circumstances, nor indeed the same plants under different circumstances, require the same amount of water. It is necessary, therefore, to study the nature and habits of kinds, so that each may be treated according to its needs. A vigorous blooming plant, say a Fuchsia or Pelargonium, might be said to represent the maximum need of water; the same when in a state of rest, in cool damp weather, the minimum requirement as to this. Therefore, to give exactly the same quantity of water in both conditions named would be to cause harm by not giving enough water to some and too much to others. One safe rule is to wait until the ball of earth begins to get rather dry, and then to give enough water to moisten the soil through and through. Then do not water again until the former state of dryness is reached, be that time six hours or six days.—("Vick's Magazine.")

— **PEAT SOIL.**—Everyone knows that there are many plants which prefer to grow in peat soil rather than in earth as we are generally accustomed to meet with it. Plants which have this preference are usually those which produce an enormous number of very fine hair-like rootlets. It is not that there is anything peculiar in the soil itself which leads to this preference, but from the often verified fact that rootlets need air just as much as do leaves. It is impossible for the plant to live without some proportion of air being absorbed by the roots. A growing plant soon dies when the roots are immersed in water. It is, in fact, smothered for want of air. Roots of comparative strength can force their way through the compact soil, so as to reach the air confined in the various pores; but the hair-like roots cannot do this. They have not the vigour necessary to force their way. Soil, therefore, which is at once moist and penetrated by atmospheric air, as peat is known to be, gives these plants an opportunity to readily make their way, a privilege of which they would be deprived in heavier soil. So it follows that the point of the superior value of peat soil for some plants is a question of atmospheric air, rather than the chemical condition of the soil.—("Meehan's Monthly.")

— **MANY VARIETIES ON THE SAME TREE.**—It has always seemed a good idea for anyone fond of variety, with a limited amount of space, to have a number of kinds grafted on the same tree. In this way an Apple, Pear, Peach, or Plum could be made to produce a varied collection; but the theory has not worked out in practice, for the reason that some varieties are constitutionally more vigorous than others, and the stronger growing varieties soon take all of the food to themselves and starve out the weaker ones. With a little good judgment in selecting varieties of uniform character, the idea may be worked out (says "Meehan's Monthly") to a satisfactory conclusion, or weaker varieties may be given a position at the top of the tree, for there is always more strength and vigour to be obtained in that position than in the lower portions of the tree. When there is little difference in the constitutional vigour of varieties, the plan may be worked out to a greater satisfaction. In the Peach, for instance, there is very little difference in the characteristic noted. Nearly all Peach trees have about the same ratio of growth, and, moreover, the Peach is inclined to be a round-headed tree, with about as much vigour in the lower branches as in the upper ones. There ought to be more success in this line of experiment with the Peach tree than with any other class of fruits.

SOBRALIA LUCASIANUM.

THE tribute paid to Sobralias by Mr. S. R. Jones, in writing for information on *S. Lucasianum*, is thoroughly deserved. When well grown they are exceedingly handsome Orchids, for although the individual flowers do not as a rule last in a good condition for a long period, fresh blooms are freely produced, and so a succession is kept up. Most of the species have brilliantly coloured blossoms, and amongst the best *S. Lucasianum* (fig. 16) must be given a prominent place. A specimen of this was exhibited by C. T. Lucas, Esq., Warnham Court, Horsham, before the Orchid Committee of the Royal Horticultural Society on June 21st, 1892, when a first-class certificate was awarded for it. This is a splendid form, the flowers being of large size. The lip is broad and somewhat flattened, soft rosy mauve in colour, the throat being light yellow. The sepals and petals are white, faintly suffused with rose, the whole making a charming combination.

SACCOLABIUMS.

Though not so popular now as they were some years ago, the species comprised in this genus are very beautiful and free-flowering Orchids, and no collection of East Indian kinds is complete without a few at all events of the better known kinds. As a rule the flowers are small, but they are produced on long showy racemes in many cases—in others they are smaller, containing fewer but larger flowers, such for instance as the beautiful *S. bellinum*. Most of the known kinds come from India and the islands about the Malay Peninsula.

Naturally, then, they require very hot and moist treatment the whole year round, but especially when growth is most active. In the majority of the kinds this is from February or March until late in autumn, and some of the winter-flowering kinds, as *S. giganteum*, may be almost said to never rest. Not only do they require heat and moisture, but an abundance of light, plants heavily shaded never flowering so freely as others kept in a good light the whole year round, and only shaded sufficiently to prevent injury to the foliage. Some do best in large pots, such as old heavy specimens of *S. Blumei*, *S. retusum*, or *S. guttatum*, but the majority are most satisfactory in baskets suspended from the roof, this, too, being most suitable for smaller plants of the above mentioned kinds.

With regard to potting or basketing, this was referred to somewhat in detail recently, and it only remains to say that the smaller the plant the narrower the receptacle should be for it. The best time either for repotting or surface dressings is in early spring just when the tips of the roots are seen to be starting into growth, and it may be noted in passing that towards the end of the season's growth these will be seen to cloud over, and when this is noticed a slight reduction in the water supply should be made. At other times the sphagnum about the roots should never be allowed to get really dry, and when root and top growth are both active a very free supply should be allowed.

This necessitates very free drainage, and the more open the material about the roots the better. During the winter months a minimum temperature of 60° is ample; on cold nights even a few degrees less will do no harm, provided it is not accompanied with too much atmospheric moisture. The only other cultural requirements are to give ample ventilation on all possible occasions winter and summer, and to see that the foliage does not get overrun with insects. Green fly sometimes appears on the flower spikes, but the worst enemy is a small scale that clings very tightly to the foliage and stems. Frequent sponging with clean tepid water is a better plan than using strong insecticides.

Of the dwarfer growing kinds, *S. ampullaceum* is one of the prettiest. It seldom exceeds 9 inches in height, and from the base of the leaves throws up a spike of rosy magenta flowers about 6 inches in height. It lasts well in good condition, and usually flowers about April or May. Though known to botanists many years previously, this was not cultivated in England until about 1837, when Gibson brought it home to the Duke of Devonshire's collection. It is a native of the lower parts of the Khasia Hills and Burmah. Another beautiful Burmese kind is *S. bellinum*, and this is a much more recent introduction, throwing fewer but larger-flowered racemes. The sepals and petals are yellowish green with blotches of brown; the prettily fringed lip is white, with a yellow centre.

S. Blumei, *S. retusum*, and *S. guttatum* are all better known as Saccolabiums, but by botanists generally are referred to Blume's genus *Rhynchostylis*. They are noble plants when well grown, the handsome foliage alone being very ornamental, while the long cylindrical racemes are second to none for beauty. Perhaps the most correct plan is to group them as varieties of one species; but they are quite

distinct, and there are also many sub-varieties, such as the large flowered *Blumei Russelianum* or the rare and valuable *B. Heathi*, a pure white form of *S. Blumei*. The usual colour of the flowers is whitish, more or less spotted with rose.

S. coeleste is also grouped under *Rhynchostylis* by Reichenbach, and is a remarkable and beautiful plant. The name would indicate that the flowers are blue, but this tint is chiefly confined to the tips of the outer segments and the lips, the rest of the flower being white. It is a native of Siam, and its usual flowering season is late summer. *S. curvifolium* is a bright and effective plant when in flower, the colour being a bright red, the racemes being erect and very freely produced. Dr. Wallich discovered this plant many years ago, but only within the last thirty or thirty-five years has it been in cultivation in England. A similar kind is *S. miniatum* (fig. 17, p. 109), introduced from Java by Messrs. Veitch about 1846. It flowers in early spring.

S. giganteum is a very beautiful large growing species now in flower. It is, perhaps, as difficult a kind as any in the genus to cultivate over a long series of years, but for a time after being imported grows and flowers freely enough. It is in flower here now, about half a dozen of the long pendulous racemes filling the house with its delicious aromatic fragrance. Disturbance at the root is distinctly harmful to this kind, and the fact of its flowering at midwinter goes against it. When imported it should be placed in medium-sized baskets or pots, and suspended from the roof. There are several varieties or nearly related kinds, such as *S. violaceum*, *S. violaceum Harrisonianum*, and *S. giganteum illustre*.—H. R. R.

SIMILARITY OF LIFE IN THE VEGETABLE AND ANIMAL KINGDOMS.

(Continued from page 54.)

ELEMENTARY CONSTRUCTION.

THE organic structures of plant life are invariably bounded by curved lines, and have their parts balanced with great symmetry; and, says Dr. Lindley, "in these respects they agree with the animal, and differ from the mineral kingdom." Romé de Lisle, in his observations upon this characteristic in the two kingdoms of life, speaks of it as "resulting from that central power of life which dilates the internal organs in all directions." In both kingdoms is equally noticeable this mysterious effort of Nature to have and to maintain these symmetrical arrangements, and even in those cases which appear to be exceptions to a natural law a closer investigation will reveal the presence of compensating influences.

This is fully admitted, in fact insisted upon by the eminent authority quoted above. This points to some inherent power which is as yet but partly revealed, although Messrs. Chatin and Moquin Tandon have studied it sufficiently to assume, what has not been generally accepted as positively conclusive, "that there are in the vegetable, as in the animal, kingdom both a centripetal and centrifugal force of development" ("Comptes rendus," v. 691). Sufficient proof, however, has been adduced from the observations of various scientists that plants possess a vital force very similar to that found in some species of animals, and further researches by M. Schultz confirm this; for although there is no heart or fixed centre of circulation, as in animals, there are certain foci from which proceed cyclosis, a phenomenon analogous to the motion of the blood in the lower forms of animal life.

In relation to this Cuvier, in treating upon respiration, says:—"No animals respire by a particular organ except such as have a real circulation, and animals which are unprovided with a regular circulating system respire like plants over the whole of their surface." The amount of time necessary to carry these extremely delicate observations to tangible conclusions is well attested by the labours of the celebrated Duhamel, who devoted thirty years to the study of vegetable physiology before publishing the principal results obtained by him. And how few of such results are accepted until others have been to almost as much pains and labour to obtain proofs.

MIMICRY.

In the case of those plants, chiefly, if not wholly, consisting of various members of the Orchid family, accredited with mimicking certain animal forms, more or less imagination is required to complete the resemblance. Selecting the well-known *Oncidium papilio* as an illustration, and which is, perhaps, as good as can be found for the purpose, we cannot, I think, but regard it as one of those coincidences which could not but occur in the vast range of life, hence it appears to me of but little or no importance. Such, however, is not the case where the animal kingdom is the primary factor, for here we find Nature employing a subtlety of design difficult to comprehend. Among some prominent examples to be found is the walking stick insect, *Ceroxylus laceratus*, and Mr. Wallace recounts an instance in which the resemblance was so close to a stick grown over with moss that a native Dyak maintained such to be the case.

It is, apparently, in the functions rather than the forms of life that plants possess the power of mimicry. The barrier may, indeed, be great between the great order of carnivora and the so-called carnivorous plants, but the functions of these plants appear to be quite on a par in the scale of intelligence with some of the lower, not the lowest, forms of animal life. One might even go so far as to say that the Sundews and similar plants exhibiting irritability in such a high degree, coupled with their powers of absorption and assimilation, compare very favourably in this respect with the mollusca or similar orders of beings, which after their infantile migrations settle for life devoid of voluntary motion.

Voluntary motion, the absence of which in the vegetable kingdom is the most important of the missing links, means the possession of

Relative to the functions of life there is one phase which, as previously remarked, appears somewhat startling, and can hardly fail to be of interest and service to the practical worker. Duhamel, Humboldt, and Plenck long suspected that plants possessed the power of voiding deleterious matter, a power common to the animal kingdom. This, in ratio to their more refined functions of food absorption and assimilation, must of necessity be obscure, yet, nevertheless, has far reaching influences. These excretions must not be confounded with the secretions of flower, or leaf, or stem, being quite distinct from them. From the suspicions entertained by the above learned trio Macaire was induced to explore the matter, and obtained sufficient proofs to leave it beyond dispute that "all plants part with a kind of fœcal matter by their roots of a nature varying with species or large

FIG. 16.—SOBRALIA LUCASIANUM.

muscles; but irritability points very strongly to the presence of nerves, which most vegetable physiologists deny, or question the existence of in plant life. In viewing the wonderful structure of the *Nepenthes*, and in considering too the climatic conditions which they love, one might be excused the passing thought that our present species are but the degenerate descendants of a type which, under contemporary conditions producing a flora and fauna now extinct or considerably modified, might even have been a terror to prehistoric man. In the matter of prickles and spines, common to various species of plants, such may be regarded without any wide stretch of imagination, I think, as a means of defence, on parallel lines to those which Nature has provided to many animals; as well as the stinging properties or irritant powers characterising certain subjects of the vegetable kingdom. In the economy of plant life we cannot find that either prickles or spines serve any other purpose, and with the former their brief duration of life, in comparison with the permanent character of the spine, leads to the inference that the protection is especially intended for immature growth.

natural orders." In connection with this may be noted the experiments and observations of Bischoff with spiral vessels, which led to the conclusion endorsed by others that their purpose in the anatomy of plant life is that of preparing the crude fluid for its nourishment and support, "just as blood is rendered fit for that of animals."

The similarity of life in the two kingdoms appears in this respect to be somewhat startling. Food to create the vital fluid, and natural laws in operation to void the deleterious matter. Upon this hinges the necessity of rotation of cropping to prevent that soil-sickness which Dr. Lindley remarks is not due to exhaustion, and that "abundant manuring will not supersede the necessity of the usual rotation." Of the interesting experiments carried out in relation to this subject one more may be noticed—viz., it was ascertained that certain plants, like certain animals, which secrete poisons peculiar to themselves, cannot absorb them into their systems abnormally without injury or death resulting. Thus, *Atropa belladonna* is killed when absorbing its own poison by its roots.—INVICTA.

(To be concluded.)

DIGGING AND TRENCHING.

SPRING v. WINTER.

THAT your respected contributor, Mr. D. Thomson's article (page 49), on the above interesting subject will be widely read cannot for a moment be in doubt; yet it must be read carefully and weighed thoughtfully. Plain and practical though it may appear, let all who have heavy soils to combat digest the matter thoroughly before acting even upon such matured advice from the pen of an acknowledged "expert." We, who are only in our "teens" as compared with the old craftsman, cannot wield the pen with the same powerful influence, the spade being more fitted for us, and we should learn to use that tool at the right season to assist Nature in her wondrous work.

I find in this, as in almost every other occupation, that individuals differ in their methods equally as much as the soils differ in character. My conviction is that no hard and fast rule can be made which will prove practicable to deal effectually with soils, so much depending on the seasons; but intelligent observation as to the character of the soil and season will prove of more value to the worker than any inflexible method. Soils during an exceptional season require exceptional treatment. Should the autumn prove dry, as was the case in 1897, I would recommend those who have strong clayey soil to work, not to hesitate, but seize the opportunity of turning it up whilst in a dry state rather than wait for what may prove a wet spring. I cannot too strongly condemn the practice of digging and trenching ground in midwinter, even though the weather may prove mild. Strong soil, such as I have to deal with, worked when in a wet state, will prove almost unworkable during the following summer.

It is a recognised fact that soil newly dug will retain more moisture than ground which is allowed to remain unbroken. Such being the case, it is difficult to grasp the "principles and laws" which govern the action of frost to penetrate deeper into a firm soil than a loose soil, for this reason, we are taught (and truly) that the drier the soil the higher the temperature, or in other words, that dry soil is always warmer than is wet soil. Therefore this point of frost penetration is somewhat difficult to comprehend from a practical standpoint. My experience with strong clay soil is that when thrown up in a rough state—the rougher the better—at any time when it is in a dry condition in the autumn, not midwinter, the greatest benefit is derived by the influence of frost and air.

Mr. D. Thomson's experience as to the pulverising influence of frost is also somewhat difficult to grasp. I gather from his article that it is a "fallacy" to believe a soil "turned up" in a rough state is pulverised by the action of frost more than is the case with soil unmoved, his experience being that unbroken ground derives the greatest benefit by the action of frost as a pulverising agent. I have no wish to dispute Mr. D. Thomson's ruling, but I ask, How are we to reconcile this with absolute facts in practice which prove the contrary? All have not suitable ground to experiment upon; but here is a case in which almost everyone interested can prove for himself. Take a large ball or lump of strong clay soil or pure clay and place it on the surface of your garden fully exposed to all weather, and then take another ball or lump, of exactly similar nature, and bury it in the soil a foot or even 6 inches deep; leave them in their respective positions until you wish to prepare the ground for the spring crops, and the result will speak for itself. The ball by exposure will be thoroughly pulverised by the action of frost and air, whilst the ball buried will, in all probability, "turn up" in much the same condition as when placed under the soil. This, at least, has been my experience.

I feel quite sure that Mr. D. Thomson will see how difficult it is for the young mind to grasp the full meaning and significance of philosophic teaching when it seems opposed to accomplished facts, but my mind is open for enlightenment.—F. DUNN.

THE MILD WINTER IN YORKSHIRE.

THE extraordinary mildness of the present winter in this neighbourhood up to now, the last day of January, is almost unprecedented. We have scarcely seen a single snowflake, and on two or three occasions only has the thermometer registered as low as 10° of frost, whilst frequently the temperature has been 40° to 45° at night, and 50° to 55° during the day. The effect on vegetation is very marked. Apricot, Peach, and Nectarine buds are swelling fast, nearly ready to open, and Plums and Pears are on the move. In the kitchen garden vegetables are looking as green and growing as if in April. Ellam's Early Cabbage, planted last September, are hearted and ready to cut.

In the famous rockery and alpine grounds of Messrs. James Backhouse and Son there are a great variety of plants in flower, in such profusion as is rarely seen, at least in the North, at this season of the year. Amongst the most noticeable are Aconites, Snowdrops, Anemone blanda, A. appennina, Colchicum crociflorum, Cyclamen coum, Doronicum excelsum, Erica carnea, Geum miniatum, Gentiana acaulis, G. verna, Narcissus minima, Saxifraga Burseriana, Pulmonaria, Rhododendron dauricum, profusely flowered clumps of Helleborus niger, H. caucasicus, H. atrorubens. And very beautiful are Iris histrioides, I. alata, and I. Bakeri, as well as a number of early-flowering shrubs. This seems all very pleasant at the present time, but old gardeners shake their heads and shrug their shoulders, indicating their anticipation of trouble ahead.—R. M., York.

THE N.C.S. AND ITS MANAGEMENT.

"AN ON-LOOKER" (page 38) is about right. Let us have a Secretary who will be the servant and not the master of the Committee, to do what he is authorised and no more. When the annual meeting takes place I trust someone will question the last balance-sheet, and perhaps the coming one too. In spite of the great assistance given the N.C.S. by the Aquarium Company the expenses are very considerable, and they still grow. In justice, it should be understood that the last balance-sheet included the receipts and expenses of the Jubilee Exhibition; but let us peruse it. In 1896 £839 10s. were spent in prizes and medals, a portion of which was met by special prizes given by various persons interested. In addition to this expenditure we have to account for £52 9s. 6d. for medals sent to the affiliated societies, for which the Society received from the said societies the sum of £109, in addition to £67 14s. 6d. as fees.

We must not overlook the fact that these societies received cards, known as "certificates," and also that, being Jubilee year, the sum of £42 was returned to these societies in the form of bronze medals. (There was no such return in 1895, when £167 was obtained from these "greatly assisted" societies, and £57 being charged in the balance-sheet as the value of the medals sent them.) It may be worthy of remark that £42 is a goodly sum to purchase about 128 medals of bronze (6s. 6d. each) and a saving may be effected here perhaps.

The refreshment account is worth a moment's consideration, considering that few, if any, of the exhibitors are ever offered a "bite or sup," as is usually the case with provincial societies who are not "supported" or "assisted" by an Aquarium Company. I abstract these items. "Luncheons to judges, floral and staff, £30 13s." The judges received, as they deserve, £33 12s. in hard cash. Annual dinner, £18 5s. 6d., and banquet £93 11s. I suppose most of the delegates from affiliated societies assisted to increase these items of expenditure, but we find nothing to this effect mentioned.

Then we have "show expenses" £51 3s., I know not what this may cover; "clerical assistance" £75, and also "clerical assistance, members' register, and extra Jubilee work" £7 7s. An item that puzzles me is "commission on obtaining advertisements" £11 5s., which many will consider should come under the head of clerical assistance, and be covered by the charge of £75; but the £11 5s. is for collecting £46 12s., whereas in the previous year 27s. only was charged for collecting £32 18s. 6d. This seems to require explanation. Now we come to advertisements £20 19s., printing £67 19s. 6d., stationery £28 9s. 3d., stamps and telegrams £36 19s., special Jubilee ditto £30.

There are items of £33 15s. to the Royal Aquarium for tickets and £19 commission on Jubilee subscriptions to the same company, and yet Mr. Dean informs the readers of the "Gardeners' Chronicle" that there are 1500 passes carrying "free" admission. Then we come to a charge of £25 for allowance for extra labour, gas, firing, and other items at the Jubilee shows. Are we not being told that the Aquarium supply most of the items free? When we consider that the working expenses of last season (1896) amount to over £700, it is difficult to find where the "great assistance and support" which we are told come from the Royal Aquarium is expended.—QUIS.

[The above letter was crowded out last week. The desirability of appointing a finance committee has been unanimously admitted by the general committee of the N.C.S., and the ratification of its proposition may be expected at the forthcoming general meeting, which will presumably be of an interesting character.]

R.A.C. (NOT N.C.S.) DIVIDENDS.

ACCORDING to the "Westminster Gazette," Mr. Ritchie, who presided last Friday afternoon over the ordinary general meeting of the Royal Aquarium and Summer and Winter Garden Society, Limited, said that "the profit of the past year, £15,998, was the highest that the Company had yet made. The St. Stephen's Hall had been put into satisfactory condition for the FitzSimmons-Corbett fight, and later on, the National Chrysanthemum Society's Show, the Dog Show, and various other shows would be held. During the past six years £60,000 had been paid in dividends, and the reserve had been increased by £20,000."

Have we not here the admission that the N.C.S. is a dividend creative medium, and relied on as a source of income by and for the R.A.C. in the same way as are shows of prize fights and dogs? It seems to be a doggy, sloggy, Mummy combination, and yet the great N.C.S. does not appear to be able to add to its reserve fund more than £5 a year. Is it not awful?

Mr. Ritchie's announcement suggests that his arrangements with the Committee of the N.C.S. for this year have been settled—perhaps a long time before the present agitation commenced, though left to the official head of the Aquarium to make the notification.

There is no knowing the ways of inner circles; and possibly it might not be altogether palatable to the N.C.S. Committee to ask its Secretary to "rush into print" with their decision. Mr. Ritchie is a very clever man. He knows how to make his "show" pay and increase "the reserve by £20,000." He has a capital Secretary, too, to whom the Committee

of the N.C.S. lately made a grant out of its funds equal to the average annual addition to its own reserve!

The N.C.S. shows seem to be placed in the arms of the Aquarium once again. It must all seem mysterious to many more than one—OUTSIDER.

CHRYSANTHEMUMS UP TO DATE.

(Concluded from page 75.)

PASSING to the selection of eighteen new varieties, the voting here gives some peculiar results. No less than 105 names are given, showing how numerous are the introductions of the last two years. It cannot be disputed that the first eighteen on the list are not entitled to their position. Here again the value of "sports" is noteworthy. The first two on the list, G. J. Warren and Lady Hanham, are "sports;" the former, as is generally known, being an offspring of the charming Madame Carnot, the latter from Vivian Morel, both models of what a Japanese Chrysanthemum should be. At least eight of the first eighteen are English raised; this fact is satisfactory, as showing that we are not now so dependent upon chance and our foreign neighbours for the introduction of new varieties as formerly.

In the selection of new ones there are numerous highly coloured varieties which cannot be other than a gain. Royal Standard, Master H. Tucker, Mary Molyneux, J. Chamberlain, J. Bidencope, and Pride of Madford. No less than thirty-eight varieties receive one vote, showing much of individual choice. It very often happens that a variety the first year is not seen outside the locality where it is grown, and although it may be deserving, there has not been time for it to receive the notice to which it may be eventually entitled. Selections such as the present one can only be of varieties which are brought more in view of the public, and in this important respect are "up-to-date."

The selection of incurved varieties reveals many important items.

VOTES FOR THE THIRTY-SIX INCURVED.

30	Empress of India	7	Robert Cannell
30	C. H. Curtis	6	Ernest Cannell
30	Princess of Wales	6	Rena Dula
30	Duchess of Fife	5	Mrs. N. Davis
29	Lord Alcester	5	Golden Nugget
29	Jeanne d'Arc	5	Mons. Desblanc
28	Miss M. A. Haggas	5	Mrs. Robinson King
28	Violet Tomlin	5	Rose Owen
28	Robert Petfield	5	Mrs. F. Hepper
28	Mrs. R. C. Kingston	5	John Salter
28	James Agate	5	Mrs. F. W. Flight
26	Golden Empress	5	John Fulford
26	Queen of England	4	Mons. R. Bahuant
26	John Lambert	4	Leonard Payne
26	Globe d'Or	4	Lyne, jun.
25	Mrs. S. Coleman	4	King of Orange
25	Bonnie Dundee	4	Harold Wells
24	William Tunnington	3	Empress Eugénie
23	Lucy Kendall	3	Yvonne Desblanc
23	Madame Darier	3	Refulgens
22	George Haigh	2	Nil Desperandum
22	Miss Violet Foster	2	Ami Hoste
21	Miss Dorothy Foster	2	J. Pearce
21	Ma Perfection	2	Princess Beatrice
20	Alfred Salter	2	Mrs. Mitchell
19	Baron Hirsch	2	Novelty
18	Brookleigh Gem	2	Miss L. D. Black
18	Mrs. Heale	2	Ideality
18	Major Bonaffon	2	The Egyptian
15	Lord Rosebery	1	Madame Mailfait
14	John Doughty	1	Mrs. D. Airdrie
14	Hero of Stoke Newington	1	General Maurie
14	Mrs. James Murray	1	C. Gibson
14	Lord Wolseley	1	Mrs. Shipman
12	Lady Isabel	1	M. Lemaille
12	C. B. Whitnall	1	King of Yellows
		1	Madame Mistral
		1	Barbara
		1	Noel Pragnell
		1	Lady Hardinge
		1	Miss F. Tomlin
		1	Mrs. James Eadie
		1	Charles Shoesmith
		1	Mont St. Eynard
		1	Triomphe d'Evé
		1	Orange Yellow
		1	Alfred Lyne
		1	Jardin des Plantes
		1	Princess Chas. of Denmark
12	Madame Ferlat		
11	Austin Cannell		
11	Princess of Teck		
11	M. P. Martignac		
10	Miss Phyllis Fowler		
10	Mr. J. Kearn		
10	Prince Alfred		
9	Lady Dorothy		
9	D. B. Crane		
9	Perle Dauphinoise		
9	Mrs. N. Molyneux		
9	Mrs. J. Gardiner		
9	Mdlle. Lucie Faure		

98 varieties.

Ninety-eight are mentioned to select the three dozen required, which gives a wide range of opinion. In spite of the fact that the "Queen" section has been considerably decried during the last two years, no less than six members of this family are found in the premier selection. That ever popular variety, Empress of India, ties with three others for the premier position, Lord Alcester, an ideal type of an incurved Chrysanthemum, being one point below. The position of Duchess of Fife in the list will, no doubt, surprise not a few. By many it is regarded as a Japanese incurved rather than a true Chinese. Amongst the electors there are those who object to C. H. Curtis, thus showing how extreme is the diversity of opinion. That ever popular favourite Princess of Wales occupies the same honourable position it has done for many years. Ma Perfection, too, is another variety that has been the cause of much comment as to its proper place, incurved or Japanese. What are known as the "Teck" family do not occupy an enviable position. The original does not obtain more than eleven votes, which is sufficient to estimate its value as an exhibition flower.

With the exception of Hero of Stoke Newington, Mrs. N. Davis, Lady Dorothy, and C. Gibson, none of the others finds a place, and those named are exceptionally low. The fact cannot be disputed that for the last five years representative blooms have been few and far between. The difficulty experienced in obtaining characteristic flowers, coupled with the comparatively small value of the section from a purely decorative point of view, has, no doubt, done much to drive the family much out of cultivation. Those old favourites, Jardin des Plantes and Barbara, find one supporter each—poor compensation after a working career extending over thirty years in the former instance, and twenty in the latter. Many more interesting comparisons might be made if space admitted; sufficient, however, has been said to show the great change that has taken place in the Japanese section, during the last ten years also the advance in the incurved over twice that period of time.—EDWIN MOLYNEUX.

VOTES FOR THE BEST EIGHTEEN NEW JAPANESE, 1896 AND 1897.

EQUAL PRIZES FOR PREMIER BLOOMS.

IN reply to the Editor's query, "Were equal prizes ever awarded in the case of the premier bloom in a Chrysanthemum show?" I can state a similar case to that quoted by "W. S., Wilts," as, at our leading district show, in 1893 (which was the first time I competed), a N.C.S. certificate and a cash prize were offered for the best bloom in the show. They were divided between two blooms, my friendly opponent receiving the certificate, and I the cash prize. This division led to much comment at the time. The next year, at the same show, I was more successful, as, with a specimen plant, I secured the cash prize offered, and better still, the coveted "bit of cardboard" of the N.C.S.—FORLORN.

[Not quite "forlorn!" If there had been no money prize with the certificate, the "bit of cardboard" itself would, presumably, have been divided, as it would scarcely do for a N.C.S. certificate to be "tossed for."]

A HANDY CHRYSANTHEMUM MANUAL.

AMONG the books advertised last week by Messrs. Blake & Mackenzie is a good little manual with the comprehensive title, "Modern Chrysanthemum Culture for the Million," by the experienced and successful cultivator, Mr. George Garner. The author says he has endeavoured to give the most important essentials in the cultivation and management of the plants and flowers in as few words as possible, and these so plain that he hopes his methods will be understood. The sixty-four pages evidently contain a narrative of his own practice from what may be described as the beginning to the end of the season of raising, cultivating, and exhibiting Chrysanthemums, or a whole year's routine. This is not done in the form of a stiff calendar, or anything of that kind, but in a series of short clear chapters. The photographic illustrations of cuttings, growths, and buds will be helpful to the inexperienced, who ought soon to be able to grow better blooms than some of those represented in the pages. The most distinct feature of this manual is the tabulated list of sixty good and generally grown Japanese and forty incurved varieties, showing at a glance the colour, height, earliness or otherwise, dates for securing buds of each, the size the blooms ought to be in the size of pots given for growing the plants. These eight pages will be tempting to many who are anxious to obtain such information as they impart. Mr. Garner meets the question of the time for bud-taking given, being suitable all round, in a delightfully easy way, for he says if the buds form later in the north than the south, the northern shows are later too, so all will come right by earlier housing in the colder districts. No doubt northerners will compare his dates for bud-taking with their own, and note agreements or divergencies. No Chrysanthemum grower can err by procuring this manual, and few, we suspect, will begrudge the sixpence. It will prove handy for reference, and afford useful guidance to those novices who would like to know as much about Chrysanthemums as the author does, who seems to tell concisely all he knows about them.

THE CULTURE OF LEEKS.

LEEKs are not so generally cultivated as is desirable, and we doubt if many of those who do grow them have them as satisfactory as they should be, even in that land of Leeks—Wales. In the northern half of this island Leeks are generally grown, alike in the nobleman's many-acred garden and in the cottager's "kail-yaird," and are appreciated alike by peer and peasant. Possibly the difference in the cooking of the two divisions of the country accounts for the different degrees of popularity in which this esculent is held. In the north vegetables are mostly used in soups, and seldom is the Leek otherwise used. "Cocky-leeky" is a favoured dish among the upper classes, but not among these lower in the social scale, and "cocky-leeky" is the only way that we know of whereby Leeks are used simply as a vegetable. In this form the flavour is too strong for ordinary tastes. In soups, even in Leek soup, pure and simple, this strong flavour disappears, and is replaced by one which few northern palates do not appreciate.

If a few necessary rules are observed in its cultivation a crop is certain, even in the least favoured positions. It is like Borecole in this, and bleak indeed must be the spot where neither will grow. For this reason it replaces Onions where climatical causes make the latter a precarious crop. It is also particularly free from insect pests, thriving where Onions are destroyed wholesale by maggots. And then every portion of the plant may be used; so it is an extremely economical vegetable to grow where ground is limited or reasons exist for growing only the most productive crop.

It is of no use attempting to grow fine Leeks on poor soil, for when stunted and starved the crop is scanty and the quality poor. The first thing, then, in the successful cultivation of Leeks is to trench the ground at least two spades deep, and to put a thick layer—the thicker the better—of rich partly decayed manure between the layers of soil, especially under the upmost one. This is for ordinary crops, for these are of the most value. To produce extraordinary crops, to furnish examples for exhibition or other extra purposes, the soil must be trenched, at the very least, 2 feet deep, and very liberally manured. To thoroughly incorporate the manure and the soil, re-trenching may be necessary.

The next point is the preparation of the plants, and various ways are in vogue among those who strive to excel. The common way is to sow the seed in a sheltered position on rich soil about the end of

February or beginning of March, or later if the weather should not be favourable at the time stated. Battering them into soil at once cold and damp will effectually prevent success. The seed, though smaller than Onion seeds, will germinate under the same conditions; but, although all the plants are to be eventually transplanted, care should be taken not to sow too thickly; indeed we are not sure but the best way is to sow in rows 1 foot apart.

In order to forward a few plants hand-glasses or cold frames are sometimes placed over portions of the bed. Deep frames should not be used for this purpose, as the plants are apt to be weakened thereby. The seeds are often sown in cold frames for the same purpose.

To prepare a large number of plants in order to secure extra fine crops, we advise those who are ambitious to excel to make a mild hotbed, and to cover it with a glazed frame about the middle of April. A strong heat is mischievous, and should be avoided. Rich soil should be used and the seeds sown thinly. Air should be given after the plants are up, and care must be taken that they never suffer by want of water. An occasional supply of weak liquid manure should be given, which will forward the plants considerably. If carefully treated they will be strong and fit to put out by the middle of May—a gain of two months, for plants raised in the ordinary way are not fit to put out till July. Two months of summer weather to grow in make a difference in the crop that needs to be seen to be believed. Leeks so raised are always of first-rate quality.

There is yet another way of preparing plants that is practised by exhibitors, by which the large specimens seen at northern shows are grown. About the beginning of February—not sooner, or the plants will be apt to run to seed prematurely—the seed is sown in rich soil in pots and placed in heat. As soon as they show the second leaf, by which time they are forming the second root, the plants are placed in 3-inch pots in very rich soil. When the roots are coiling in these they are shifted into 6-inch pots. They are kept near the light, and occasionally given a little sulphate of ammonia.

By the middle of April they will be fit for hardening. Do this by disposing the pots in a frame into which a foot or so of hot manure has been placed. This will maintain a temperature nearly equal to that to which the plants have been accustomed, and as it cools the Leeks will harden. Then ventilation should be increased for a week or two, when the plants will be ready to put out. Instead of using pots for the plants they may be pricked into boxes, but in transplanting a check will be given, whereas when pots are used no check is given; at the same time we have raised many fine Leeks in this way. Melon pits, Cucumber frames, and other warm structures, too warm for forwarding any other hardy vegetables, will do capitally for Leeks if they can be well exposed to light. A high temperature will ruin Cauliflowers or Celery in a few days, but will benefit the Leeks. Those, therefore, who can neither spare manure to make hotbeds nor afford cold frames for this may utilise any spare room at their disposal.

Do not plant the Leeks among the Celery, and do not plant them in trenches like Celery. Earthing them is a mistake; nobody ever produced good Leeks in that way. Again and again we have been shown Leeks grown on the Celery-trench principle, but they were not satisfactory. The secret lies in obtaining strong plants, put out deeply on well-prepared soil, at a time when ordinary growers are watching theirs coming up.

For ordinary crops there is no better way of planting than the old-fashioned one of making holes with a dibble a few inches deep (that is, down to the layer of manure under the upper spade of soil), and dropping the plants into them singly, but putting in no earth except that which falls in of itself. The hearts of the plants will be much below the surface, but that is just what is wanted, for the hearts will come to the surface, and so the stems will be drawn out to the same length as the hole is deep. We need hardly add that the long blanched stem is most valued, but we warn beginners that the stems can only be lengthened by deep planting. When once the plants have grown strong earthing will not cause the stems to elongate.

The plants in pots must be placed in holes dug with the spade. This digging loosens the soil, which would fall into the centres of the plants and spoil them, but this can be prevented by putting a stiff paper funnel round each plant. In a week or two the stems will be drawn so that the centres will be at the surface, when the funnel may be removed.

Leeks raised in the ordinary way may be planted in rows 14 inches apart, those on a hotbed 2 feet apart in the rows and 1 in the rows, pot plants 2 feet each way. A thick mulching in hot summer weather is of great benefit, and when the soil is fairly well filled with roots a thorough soaking of weak liquid manure will produce surprising growth. Nothing is better than diluted drainings from stables or cowhouses, but sulphate of ammonia is very good.

In preparing the plants for exhibition they should be carefully lifted with all the roots entire, one or two of the outer rinds being removed from the stem, for these are generally yellow, and dirt is almost always seen shining through. Closeness of texture, solidity, purity of white, straightness, uniform thickness, and length of blanched stem, are the points aimed at by those who engage in Leek-growing and exhibiting.

Anyone who finds himself in spring with a number of Leeks running to seed need not conclude he is going to have a great loss. If the seed stems are pinched out the plants will form bulbs at the roots like Onions. These are preferred by many to either Leeks or Onions as a vegetable when stewed tender and served with roast meat.—AN OLD GROWER.

THE MANURIAL VALUE OF SOLUBLE PHENYLE.

THE practical experiences of Mr. W. Iggulden with soluble phenyle are most interesting, and as my remarks on the subject appear to be out of accord with practical results, I would ask your indulgence for a few more words on a subject upon which I was rash enough to embark. It should be understood that I am only interested in the scientific facts at stake, and that I am willing to accept anything if it can be proved experimentally.

First let me remark that the original advice given to your readers was that of using 1 gallon of phenyle in 100 gallons of water. Mr. Iggulden uses apparently a tenth of this strength, and is now about to employ a dose $\frac{1}{20}$ th of the original strength recommended. Surely it is desirable for your readers to be in possession of two facts.

(1) What is the weakest strength required to kill eelworm in infected soil?

(2) What is the strongest dose (a) a Tomato, (b) Cucumber, (c) Cyclamen will stand?

My opinion—and it is only an opinion—is that so dilute an application as 1 gallon in 2000 gallons would not kill anything, much less an eelworm.

That eelworm can be cured by this substance I have no reason to doubt, but I am anxious to know if it can be applied safely at a killing strength. If this be established, soluble phenyle will be a great boon to gardeners.

I am not yet convinced about the manurial benefit. From Mr. Iggulden's statements as to the manuring of his Tomatoes he gave them half a ton of kainit, half a ton of "super," and a ton of soot per acre, besides a liberal supply of dung (40 tons per acre), also frequent doses of nitrate of soda and soot. This manuring is well arranged, and the only item in excess is the kainit, which certainly is in unnecessary proportion. Mr. Iggulden makes ample provision for the largest crop of Tomatoes it is possible to obtain, and, moreover, in the form of the cheap substances any agricultural authority might recommend for the purpose.

We are told that watering these plants with soluble phenyle, 1 gallon in 1000 gallons, "is well worth its cost as a manure alone." The price being 6s. per gallon, we arrive at a cost of £60 per ton for this novel fertiliser. If it be prepared according to the patent specification its manurial value to ordinary people would be 4s. a ton, or a farthing a gallon.

I repeat, I cannot accept this statement and refuse to believe in the "manurial" benefit of soluble phenyle until it is supported by more than the evidence brought forward. To prove such a point as this some standard of reference is necessary. Say, ten plants watered with pure water, compared (by careful weighing of produce and leaf and stem development) with ten plants identically treated in every detail except the watering with phenyle.

I could quote dozens of statements by some of the best gardeners in England about the effect of patent manures to show how fallacious is the plan of growing crops in the richest and best soil, and then applying a particular dressing to the whole extent of the crop without leaving a portion undressed for gauging the effect of the material applied. "The best crop of so-and-so I ever grew received such and such a substance, therefore it is a splendid and effectual material for producing good crops." Let us have some checked experiments on the effect of phenyle, and place the matter beyond the present state of mere opinion in which it rests. We shall then get a clue to the "something wrong."—HALOGEN.

AMPELOPSIS VEITCHI (TRICUSPIDATA).

PROBABLY the most popular and widely grown hardy wall climber is the Japanese Ampelopsis which bears the above name. Its attractiveness of foliage and neat regular habit of growth place it far above any other variety of Ampelopsis for furnishing smooth surfaces, and superior to any deciduous climber grown simply for ornamental foliage. It also has the merit of being easily cultivated in almost any position or aspect. Shady and sunny walls alike seem to suit it when once it has become established, and obtained a good start in moist soil of a fair depth. It is most vigorous and free, making frequently many square feet of growth, which not only covers, but effectually clothes the space furnished annually.

The best time for planting is in mild weather at the present season, though autumn is a suitable time. Good plants may be procured in 5-inch pots, and these are better than larger. Those which will cover a large space at once are difficult to establish on the wall space, as it is important that the growth should at first be secured until the young shoots have extended and put forth their tendrils, furnished with peculiar sucker-like claws, whereby the shoots attach themselves to the surface of stone, brick, or wood. Being so plentifully provided with these suckers is the chief reason why the growths so closely adhere to the smoothest surfaces without constant attention in fastening with nails and shreds. Practically, then, after the first nailing there is little or no trouble in training, and plants may be left to themselves, when they will cover the available space thickly, but gracefully, spreading in all directions.

Ordinary fertile soil, that is moist but well drained, forms a suitable medium for planting. In the preparation of the site deep digging is the best means of bringing the soil into condition. If poor add well-decayed manure, and intermix leaf soil and loam with the surface to further improve it. If of a rather heavy and clayey character, gritty material

and old potting soil prove beneficial in assisting the roots to make a good start. It is desirable that the site should be away from the impoverishing influence of tree roots. It is difficult to establish the Ampelopsis quickly where the roots of large trees abstract moisture from the soil, while the foliage of the same trees may prevent rain reaching the soil in summer.

The positions chiefly selected are at the base of buildings, villa residences, cottages, gable ends, or walls of any height. No climber is better adapted for furnishing lofty walls luxuriantly and drooping gracefully round windows, over porches and doorways in the summer

FIG. 17.—SACCOLABIUM MINIATUM. (See page 104.)

months, while in winter the outlines of the slender stems on the walls are no mean ornament.

When planting turn the plants out of the pots, keeping the ball of soil intact with the exception of just loosening some of the matted roots round the bottom and sides. Spread out the loose roots to their full extent, and work among them some fine loamy compost. The rest of the soil may be filled in and made firm. A mulching of manure in a half-decayed condition will keep the soil moist for a considerable time. During the driest weather copious supplies of water may be given to promote growth during the first season, but little assistance ought subsequently to be needed. The roots ramble a long way in search of sustenance.

The vivid colouring of the leaves in the autumn is a characteristic which further recommends this Ampelopsis. Shortly before the leaves fall they assume various tints of colour, beginning with coppery brown, and ending in vivid crimson.—E. D. S.

NOTES ON CAMELLIAS.

So much has been said about this noble flower at one period or other that it requires what is termed "pluck" to approach the subject. Still we must consider the propriety of addressing new readers, as well as of reminding, occasionally, old readers.

Our Camellias are at this time exceedingly fine. We have some 18 inches in circumference; and even *Donckelaeri*, which is not usually a large flower, 15 inches. The plants are covered with buds of enormous size, perhaps scarcely a shoot but is studded, and in another week or so we shall have hundreds out, to all appearance; the foliage, too, of the deepest glossy green. And to what is this attributable? Not to what is termed pot-room, certainly, for we are no great advocates of big pots for Camellias. It is to the use of turfy soil, to the judicious application of liquid manure, and to the preservation of, perhaps, an unusual amount of air-moisture. We also use a very considerable amount of water to the roots, perhaps more than most cultivators; but as the quantity to be used depends so much on the roots, the constitution of the soil, and the drainage, we must again refer to that part of the affair.

It must not be inferred from these remarks that we continue to use, unguardedly, so great an amount of air-moisture when they are in blossom and in the dead of winter. We do use a little constantly, even then, but it is ever accompanied by some degree of ventilation.

The quantity and frequent application of liquid manure which Camellias in a healthy state, rather "pot-bound," and full of bud, will enjoy is amazing; they are a match for Roses, or, indeed, any other plant, in this respect. But we always use it perfectly clear and weak. I really cannot say with precision what the rate of guano per gallon is, but should imagine it is about half an ounce; this will appear a small quantity to some, but then, it must be observed, we seldom use water alone from the time the blossom buds are as large as Peas until they have done making wood. I have never found anything better in this way than good Peruvian. I have tried soot, manure-heap liquor, and soapsuds, but they are rather more difficult of application, and not so certain in the result required. Soot, however, may be used, and with benefit, if necessary; and in that case I should say that two parts soot to one of guano would be good. Soapsuds I have a decided objection to; they not only produce an unsightly appearance, but they are quite at variance with our fundamental principle of high culture by partially closing the pores of the soil, for they always leave a scum or skin behind; otherwise there is no doubt about their possessing manurial qualities. Soapsuds appear to me as fitter for manure heaps, or to apply to growing crops just before a hoeing or other cultural appliance.

But in the use of very fibrous soil, as being so durable in texture, and less likely to derange the drainage, I place very much stress. I have been so particular as to this with mine, that after being chopped roughly I have sifted it, rejecting all the fine soil which came through the sieve, and after drying the lumps have shaken them once more in the sieve, thus leaving a great amount of organic matter in a very porous condition. In the act of repotting these lumps are crammed in tightly as the potting proceeds; but, be it observed, they are in a dryish state, or the tight cramming could not be recommended.

I may here observe that this porous character of material, together with the most secure drainage, have been found particularly requisite, as connected with the liquid manure, the object of which is to sustain annually the greatest amount of the finest blossoms, with the noblest character of foliage. The pots or tubs should be so drained that no sediment can possibly insinuate itself amongst the drainage; and must be also durable in character, according to the size of the shift, inasmuch as the larger the shift the greater is the probability of the tree remaining in the pot or tub.

I have known several cases of such a derangement of drainage as would cause the water, when applied, to stand on the surface of the soil for half an hour after being applied, and unless speedy relief were given, the sure consequences always were, the whole plant becoming pale in the foliage, and accompanied by a kind of vegetable emaciation.

It is amusing to see the speedy and equal passing of moisture through the soil of plants potted on the principles here recommended, as compared with those in which the soil has become soured. The water, applied ever so copiously, disappears in a few seconds, and its mode of vanishing, like the famous dissolving views, is so stealthy, that you seem surprised at beholding naked soil, which was a moment before a sheet of water. To some this may seem making a great deal out of a small matter, and if the principle began and ended with the Camellia, I would confess to it; but I stay for a moment to observe, that so small an affair may point to great matters, as concerns the cultivation of the soil of our broad and fertile acres. Does it not point to the immense importance of organic matter in the soil; as also to the benefits derivable from high cultural processes as to the free and equal transmission of moisture?

But to return: let me remind your readers who desire to shine in winter Camellias of the great importance of early growth. Hurrying them into growth causes such an off-hand development of the parts, such a speedy expenditure of the forces of the tree already stored up, that no after tendency exists for a second growth, to anomalous formations, or to barrenness. The growth completed by about the end of May, a long period remains for the proper formation of the flower bud, and I have always found that the steadier this process proceeds, the bolder and better coloured will be the flower, and the more certain and easy the development of its parts.

During the blossoming period, no vapour should be permitted to condense on the blossoms; their purity and endurance would be much

injured thereby. I have a fine Camellia bush, which last year continued in blossom from the beginning of November until the end of February, or even longer. This shows how long the flowers may be continued on one tree only. The same tree is now in full beauty, bearing a score or two of flowers. I have a small fire night and day, the houses freely ventilated constantly, day and night, and water used liberally, morning and evening, about the floors; but still, through the ventilation, not a drop rests on the blossoms. Let me again recommend those who do not well understand this invaluable winter flower, this bouquet favourite, to shape their practice in this manner.—E. R.

LONDON'S OPEN SPACES.

A GENERAL SURVEY.

It is related that Pitt, afterwards Earl of Chatham, was once asked by Queen Caroline, the Consort of George II., how much it would cost to shut the London parks away from the public, and to convert them into absolutely private property. He replied, "Three crowns, your Majesty." The hint conveyed in these words was understood, and the design was never afterwards entertained, for says another writer of the time, "The people are greatly jealous for the preserving of open places." Yet they knew not London as we know it now, and many of the busiest and most crowded portions of the great metropolis to-day were then open country. In the time of the Second George, for instance, St. John Street Road, with Goswell Road, formed the only outlets practicable for carriages from London to Islington and the Great North Road. The district was full of fields and muddy lanes, and the roads so dangerous that it was customary for travellers approaching London this way to remain all night at the Angel Inn, rather than venture to prosecute their journey after dark at the imminent risk of being robbed by footpads, or falling into some of the filthy quagmires and stagnant ditches that lay in every direction to trap the unwary traveller.

Looking from Holborn Bars the spectator gazed upon a long stretch of country, full of green fields and marshes, and dotted here and there with farmhouses. Yet even then the necessity of breathing-room for London was recognised, and a writer of the day says, "It grows apace, this monster of stone and brick. Every day some fresh encroachment blots out with burnt clay a greater space of country—green has become black, the air is foul with smoke, and if we do not preserve our breathing places from the builder we shall die choked." The necessity of keeping open spaces in the midst of the metropolis was thus early recognised, though dimly, as a sanitary precaution, but the glory of giving London pleasant open places for health and recreation's sake belongs practically to the latter years of the present reign.

The Royal parks in the metropolis, St. James's, Green, Hyde and Regent's parks, the latter of which, by the way, came under public control in 1812, are, of course, amongst the finest of our open spaces, but were found by no means sufficient for the public wants, so public bodies and private benefactors began to inaugurate the magnificent series of parks and playgrounds for the people that are the pride of Londoners to-day, and the majority of which are so admirably kept and governed for them by their representatives on the County Council. In 1887, marking the year of Jubilee, the London Parks and Works Act placed the great spaces of Battersea Park, Kennington Park, Bethnal Green Museum Gardens, Chelsea Embankment, and Victoria Park under municipal control, the immediate authority being vested in the Metropolitan Board of Works, which in turn handed them to its successor, the London County Council. The parishes in which the larger spaces lie are twenty-two in number; Bethnal Green has Victoria Park, 244 acres, and Victoria Park Cemetery, now laid out as a public garden of 11½ acres; Camberwell has Peckham Rye, 112 acres, Dulwich Park, 72 acres, and Myatt's Fields, 14½ acres; Hampstead has Hampstead Heath and Parliament Fields, some 550 acres; Islington rejoices in Finsbury Park, 115 acres, and Highbury Fields, 27½; Kensington has, of course, Kensington Gardens, 275 acres; Lambeth has Brockwell Park, 73 acres, Kennington Park, 19½ acres, and Vauxhall Park, 8 acres; Marylebone has Regent's Park and Primrose Hill, 473 acres; St. Pancras has Waterlow Park, 30 acres; St. George's, Hyde Park 361 acres; Hammer-smith, Wormwood Scrubbs, 193 acres, Old Oak Common, 104 acres, Ravenscourt Park, 32 acres, and Little Scrubbs, 22 acres; Greenwich, Greenwich Park, 185 acres; Hackney, Hackney Marshes, 328½ acres; Stoke Newington, Clissold Park, 53 acres; Lewisham, Blackheath, 267 acres; Rotherhithe, Southwark Park, 63 acres; St. Martin-in-the-Fields, Green Park, 54 acres, and St. James's Park, 93 acres; Clapham, Clapham Common, 220 acres; Tooting, Tooting Graveney and Tooting Bec Commons, 63 and 144 acres respectively; Streatham, Streatham Common, 66 acres; Battersea, Battersea Park, 198 acres; Wandsworth, Wandsworth Common, 183 acres; and Plumstead with Bostall Heath, Bostall Woods, and Plumstead Common, 55, 61, and 100 acres in extent respectively.

These parishes have, in addition to the large open areas quoted, numerous smaller ones, varying from one-quarter to 16 acres in extent, while most of the other London parishes have open spaces of some kind from 100 square yards to 2 acres in extent. These spaces are vested in various authorities, of which the London County Council is by far the most important, controlling, as it does, seventy-nine, representing 3685 acres of the total under all authorities in London parishes; which, leaving out Wimbledon and Putney, whose commons of 1412 acres are under special conservators, amounts to 5449½ acres. In March, 1892, the Council's return of the number of acres it held as open spaces was 2656,

so that it is apparent by the figures previously quoted that no opportunity has been neglected of making acquisitions to satisfy public needs in this direction. The expressed wish of the Chairman of the Council that the natural boundaries of our county should be "a belt of green spaces, providing ample ramparts of fresh air," is one every thinking inhabitant of the metropolis will fervently echo. Such public parks and gardens are all of the utmost value as factors in the making of a healthy community, while, in addition, historical and romantic associations of the greatest interest cling round many of the older ones, concerning the most important of which it will be the province of succeeding papers to treat.—("Lloyd's News.")

THE YOUNG GARDENERS' DOMAIN.

THE PAST, PRESENT, AND FUTURE.

I READ the "Young Gardeners' Domain" with the greatest of pleasure. The writers often make me revert in thought to the time when I was young, when I began to take an interest in the cultivation of the soil, to wish that I could have availed myself with but a tithe of the advantages offered to youths of the present day. Gardeners of seven decades ago were, as a rule, an undivulging people. One might be famous for this, another for that; but rarely would they impart their secrets for others. Oh! it was hard searching work for such as me; for very sparse was the horticultural, or any other periodical literature then. I do not want to sermonise, but now that young men can claim so many advantages in the above respects there must be great hopes for the future, and the benefit ought to be great since editors open their pages and lend an encouraging corner. My incognito of "Upwards and Onwards" took a place in these pages very many years. I now say, "Go on young men after that impulse, both in heart and deed, and then there is no fear for Britons maintaining their forefront position."—ROBERT FENN.

[We place the "oldest contributor" at the head of the young aspirants. All of these have opportunities for self-improvement such as the senior never had, but we fear that few of them are endowed with the spirit of patient plodding perseverance which has enabled him to accomplish so much as the father of our present race of Potatoes (for he was the Columbus) in keeping himself young and making himself happy in his eventide of life. Some young men start bravely—perhaps at too high speed; but if all who halt spend their time as well as one of them, as indicated in the following extract from his letter, we shall be abundantly satisfied.

"I am sorry to say I have not been able to do much writing in the 'Domain' lately, but I have been too busy otherwise, as I am attending various classes, and that necessitates a certain amount of home work. I am attending these classes, for I know they will be greatly to my advantage in after years, for I am determined to let no opportunity pass which affords a good chance of aiding my advancement. In the shorthand classes I am getting on well. I nearly always obtain the highest number of marks for home work, and as there are about thirty in the class, chiefly clerks, this is thought a creditable performance. I have also been busy writing essays, and I intend sending you transcripts of good papers which have been read at our Society's meetings."

That is the right spirit to cultivate, and the tone displayed in the letter will please the octogenarian.]

CHRYSANTHEMUMS FOR LARGE BLOOMS.

THE mild weather of the past few weeks has hastened the rooting of the cuttings, and it is therefore advisable to examine the plants, and all that are rooted through must be removed to a cold frame and kept close to the glass. To insure sturdy growth give a little air on favourable occasions. Some growers put several cuttings round a small-sized pot, and these should be potted singly as soon as rooted, but the better plan is to root them singly in "thumbs," as they thus receive no check in repotting.

A compost found suitable for this first potting comprises equal parts loam and leaf mould with plenty of sand. See that the pots are thoroughly clean and properly crocked; keep the frame closed for a few days, spray them over on fine days, afterwards giving a thorough watering. Air should be carefully given at this time of the year, and it is good practice to fumigate the plants about every three weeks, as prevention of an evil is better than cure.

A few cuttings should be inserted now of those varieties which come too early for the first crown bud and too late for the second, as unless you secure the bud at the right time you cannot get first-class blooms. Though I do not propose to mention varieties, I should like to say a word for Simplicity, a grand white, which requires very careful cultivation. The buds must be taken about the middle of August, as those give the best blooms, while feeding must be very moderate, or the buds may decay when about the size of a nut.—GROWER.

FLOWERING SHRUBS—DESFONTAINIA.

DESFONTAINIA spinosa is a shrub too seldom seen. It somewhat resembles a Holly, and is at times mistaken for one; it is, however, dwarfer in growth than the Ilex, seldom exceeding 4 feet in height or diameter. It is very effective in the shrubbery when the golden yellow flowers glisten among the dark green Holly-like leaves.

The Desfontainia, being a slow grower, is adapted for greenhouse or conservatory decoration, and is one of the best hardy plants I know for that purpose. It comes into bloom during the month of August, and continues about six weeks. The flowers are tubular in shape, about

2 inches long. There is no other species so far as I am aware besides the one named, though there are synonyms. The Desfontainia succeeds in ordinary fertile loamy soil.

For pot culture a compost of two parts loam, one of peat, and half a part each of sand and leaf soil answers admirably. Good drainage is essential, as the plants dislike a stagnant soil, but all the same they require a liberal supply of water during the summer, less sufficing in winter. Repotting may be done either just after flowering or early in spring.

Propagation is effected by cuttings towards the end of August or early in September, inserted singly in small pots in a mixture of sand, leaf soil, and loam in equal quantities. A little heat facilitates the rooting process, but the cuttings will emit roots in a cold frame, if kept close and shaded for a time. They should not be disturbed until April, when the plants may be potted and grown in a frame. Plants thus raised require to be grown for two or three years before they will be fit for planting in the shrubbery, and rather longer before they will make good specimen plants for the greenhouse or conservatory.—EDINBURGH.

[A peculiarity in spelling in this generally well written letter, consisted in the plant resembling a "Holy," as having "Holy"-like leaves. It will be well to abandon the habit before it gets as firmly fixed as in the case of a voluminous writer on gardening for twenty years, who always calls a spade a "spaid."]

CROTONS.

THESE are amongst the most valuable foliage plants we have, both for grouping and table decoration. I think there are few plants look better on the dinner table than some of the fine-leaved varieties, such as angustifolius, Wilsoni, interruptus aurea, and others, with their bright graceful leaves.

A good stock of young plants may soon be obtained by taking the tops off old plants and inserting them in thumb pots filled with soil, consisting of half peat and half loam, finely sifted, and plenty of coarse silver sand; place the pots in the propagating pit, which keep close until the cuttings are rooted, syringing them once or twice a day. Another method of increase is known as the ringing system. Cut through the bark of a shoot, and peel off about an inch just below a joint, and secure round the cut a small handful of moss, with a little fine soil and coarse silver sand. Keep the moss damp, and the shoot will soon root into it, when it may be taken off just below the roots, and put in a pot.

The old plants may then be cut back, and will soon make fine heads again. A suitable compost for potting them is two parts each of peat, good loam, one of leaf soil, and one of silver sand. When the pots are filled with roots liquid manure may be given once or twice a week, with good results, especially weak cow manure or soot water. The temperature of the house should not be allowed to fall below 60° at night, with a rise of 10° on dull days, and allowing a further rise to 85° or 90° with sun heat. Syringe the house and plants well in the morning, and again in the afternoon on bright days, and keep the air moist by damping the floor.—W. W.

BIGNONIA VENUSTA.

THIS is a plant about which one hears very little, and I give the following few notes regarding its culture. It is a greenhouse climber, bearing orange-scarlet flowers, and occupies the roof of a lofty intermediate house facing south-east.

The plant in question is growing in a prepared border 3 feet square. Last year the border was top-dressed, and liquid manure and soot water given throughout the growing season. This year, however, the border will be enlarged when the plant has finished flowering. As the growths were made the strongest were secured to a wire trellis 1 foot from the glass, and the strands wide enough apart to insure the thorough ripening of the wood, which is a very necessary point; for if the main shoots be not properly matured the lateral growths which proceed from them will be sappy, and not flower well. It was for this reason that a south-east aspect was chosen for this specimen.

For the last six weeks the effect of this plant has been grand, and there is every appearance of its continuing to boom for many weeks longer. It hangs down from the roof in long festoons, the clusters of orange-scarlet flowers springing from the axils of the leaves. Propagation may be effected by means of cuttings taken off with a heel and inserted in thumb pots, using a sandy compost and plunging the pots in a moderate hotbed. Those intending to plant, however, would do well to purchase a plant from a good nurseryman in preference to rooting cuttings, planting in a well drained border in a compost the staple of which is good rich loam with some peat and leaf mould added, and enough sand to keep the whole porous.

Bignonias, as a rule, are not subject to attacks from insect pests unless placed in direct contact with infested plants, when they will, as a matter of fact, soon become contaminated. Long sprays are very useful for house decoration, and last a considerable time in water.—T. P.

GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Secretary, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—Secretary, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—Secretary, Mr. A. F. Barron, The Royal Gardeners' Orphan Fund, Chiswick, W.

FRUIT FORCING.

Cucumbers.—Young plants are now ready for transferring to the hillocks in the Cucumber house, it having been thoroughly cleaned, and the soil placed in a few days previously to become warmed. Press the soil firmly about each plant, place a stick to each, and secure it to the front wire of the trellis. If bright sunshine occur, shade lightly in the middle of the day to prevent flagging, and after the plants become established it can be discontinued, subjecting the plants to the full influence of the sun. Keep the night temperature at 65°, falling to 60° on cold and rising to 70° on mild nights, and 70° to 75° by day, with 80° to 90° from sun heat, closing early in the afternoon, with plenty of atmospheric moisture on fine days.

Winter Cucumbers, or plants in bearing, will require copious supplies of liquid manure in a tepid state, affording occasional top-dressings of sweetened horse droppings and a sprinkling of soot. The advertised fertilisers are also excellent for top-dressing, supplying a little fresh loam as a rooting medium, an abundance of roots being necessary for imbibing food. Crop lightly, and keep the plants free from insect and fungal pests. Avoid overcrowding; let the foliage have full exposure to light; remove bad leaves and exhausted growths, stopping others one or two joints beyond the fruit as space allows, and maintain a supply of young growths for successional bearing.

Cover manure frames with double mats at night, the linings of the beds being attended to weekly or fortnightly, according to the state of the weather, keeping a supply of stable litter and leaves in readiness for that purpose.

Cherry House.—The Cherry is impatient of fire heat in the early stages of growth, and requires abundance of air. This is an important matter; therefore, commence ventilating at 50°, allowing an increase to 65° with proportionate ventilation, closing the house at 50°, 45° being sufficient by day artificially and 40° at night. The trees advancing slowly from the end of last or beginning of this year are now rapidly unfolding their buds, those previously forced coming into blossom, and will soon need attention in fertilising the flowers on fine days, using a camel's-hair brush, rabbit's tail mounted on a stick, or a bunch of feathers. Where the flowers are not expanded it is well to fumigate the house with tobacco or vapourise with nicotine, so as to make sure that the trees are free from aphides, repeating at intervals of a day or two once or twice. The borders must not be neglected for water, giving a thorough, but not an over supply, as necessary. Trees in pots—a very desirable mode of securing early Cherries—will require more frequent attention.

Melons.—The early raised plants will now be ready for planting out, and require similar treatment to Cucumbers. Excellent Melons are grown in pits, with hot water pipes for top heat, and the bottom heat furnished by fermenting materials. Stable litter and an equal proportion of Beech or Oak leaves should be thrown together about a fortnight before they are required, thoroughly incorporating them, and if dry they should be moistened. In a few days it will be seen whether there is moisture enough to produce fermentation; if so, turn the materials, before violent heat is produced, outside to inside, and damping any dry materials; but if the heat does not generate quickly, the material must be turned after a few days, and receive water as required.

In making hotbeds for frames—still a very desirable means of growing high class Melons—always select a dry site or employ a good layer of faggots for the foundation, taking care to make the bed large enough for the season: 5 feet high at the back and 4 feet in the front, with the material well heated down, will not be too high. Place the frame on the bed, and in four or five days level the surface by adding the requisite quantity of fresh material, and place in the centre of each light about a barrowful of soil in the form of a flattened cone, the top about 1 foot from the glass. When the heat does not exceed 85° to 90° place out a plant in the centre of each mound, pressing the soil firmly around the ball, taking care not to injure the stem, and a little dry soot drawn in a ring round each plant will protect it from slugs.

The day temperature in either houses, pits, or frames should be 70°, 80° to 90° from sun heat, losing no opportunity of admitting a little air, especially in frames, to allow of the escape of rank steam or accumulated moisture, but in no case must the air be admitted so as to lower the temperature below 70°. The night temperature should be 65°, 5° less on cold nights and 5° more when mild weather prevails. Instead of planting out too soon shift into larger pots as required, plunging in a bottom heat of 80°, securing the stems to small stakes, and rubbing off the laterals to the height of the bottom wire of the trellis. Plants for pits and frames should be stopped at the second rough leaf.

Peaches and Nectarines.—*Earliest Forced House.*—The maintenance of a comparatively low night temperature and a steady heat by day are essentials of safe advancement, and attention to fertilising the flowers, especially that of crossing, where there is a deficiency of pollen for securing a good set of fruit. In the case of late varieties still in flower they may have the camel's-hair brush, or other means of distributing the pollen, passed over them, keeping the house moderately dry with a circulation of air until the petals commence fading, when a slight syringing

with tepid soft water will soon bring off the remains of the floral parts. Inside borders are a great advantage in early forcing, the trees always succeeding better than when the roots are in cold outside ones, and the fruit sets better in a lower temperature under those circumstances. Lost time (apparently) can be made up as the days lengthen and brighten; undue haste in early forcing often causes the loss of the crop.

Proceed cautiously with disbudding, also shorten shoots that were left at full length at pruning time if the setting is not good at the points. Remove the foreright shoots first, commencing at the most upright part of the trees, and work down to the horizontal branches at the base. Keep a sharp look out for aphides, and fumigate upon their first appearance. Be careful, however, not to give too much, as the foliage and tender fruit are very susceptible of injury. See that all surfaces near hot-water pipes are kept constantly moist, and that the roots of the trees are well supplied with water or liquid manure in a tepid or weak state. Avoid, however, over-excitement in the early stages of swelling, which is often fatal to stoning. Admit a little air on all favourable occasions, but be careful to avoid cold currents, and close sufficiently early to raise the temperature a little, or maintain a good heat for some time after closing, there not being anything like sun heat, avoiding a close atmosphere by a little ventilation constantly.

Succession Houses.—When the trees are approaching the flowering stage syringing must be discontinued, but secure a genial condition of the atmosphere by damping the house occasionally. In other cases syringe in the morning and afternoon until the flowers commence opening, and in case of a great show of flowers remove those on the under side of the trellis. Do not omit to fumigate on a calm afternoon to destroy aphides that may exist; they hibernate in the eggs and emerge about the time the trees burst into flower and leaf. Brown aphid, however, lives on the young wood through the winter, and patches of it should be treated with tobacco water or other insecticide, sparing no effort to keep the trees free from these pests until the flowering is over; then they can easily be kept under by approved means, not so whilst in flower. If inside borders be dry afford a thorough supply of water or liquid manure in the case of weakness in the trees.

Later Houses.—The mild weather has not made much difference in the trees, they appearing to take what they are always the better for—namely, a period of apparently complete rest. Avoid dryness at the roots, affording thorough supplies of water or liquid manure, not, however, making the soil sodden by needless applications. Where the roof lights have been removed the borders will have been well moistened by the recent rains. Ventilation will be necessary to the fullest extent, so as to keep back the blossoms, and the roof lights should remain off until the flowers are emerging from their scaly covering, and not then safe from frost.

THE KITCHEN GARDEN.

Broad Beans.—When the ground is very cold and wet seed sown before the second week in February is liable to fail. This season, up to the time these hints were penned, the weather has been singularly mild, and the ground, as a rule, is neither so cold nor wet as usual. If, therefore, it is still in a favourable condition, seed may well be got in at once. If extra early crops are desired, and the space can be afforded, sow on a sunny border, previously manured and dug. Rows sown at the same time in the open quarters will only be a few days later. The Early Longpod type crops heavily and ought to be sown now, and with these Beck's Dwarf Green Gem, the best in point of quality.

Early Peas.—The remarks upon early sowing in the case of Beans also apply to early Peas. Only the nearly or quite round-seeded varieties should be sown thus early, as we may yet have severe frosts, snow, and cold rain. If the ground cannot be got into a finely divided state it should be chopped to pieces as much as possible, the two-tined Canterbury hoe proving a good tool for the purpose. Sow the seed rather thickly, allowing for some failures, and cover with 2 inches of fine soil.

Peas without Stakes.—Stakes are not indispensable in gardens, and are rarely used in the open fields. Any dwarf or medium height variety will succeed well in a garden, and under field culture stakes are not required for such tall-growing varieties as Telephone and Duke of Albany. If this plan of growing Peas is adopted the seed should be sown in a single narrow line, much as Broad Beans are sown, and the drills ought to be from 2 feet to 30 inches apart. When sufficiently advanced in growth the rows should be moulded up. Unstaked Peas form the least haulm, but crop early and heavily.

Spinach.—The mild winter has been favourable to the steady growth of autumn-sown Spinach, and may also lead to the plants running to seed earlier than usual. In any case, more seed should be sown in order that there shall be no break in the supply. Between the rows of Peas that are to be staked may be sown single lines of Spinach, one crop not interfering with the other. Clear away weeds, afterwards distributing soot between the rows, and stir it in with a Dutch hoe.

Early Potatoes.—It is yet early to commence planting Potatoes on a large scale, but small breadths on warm borders, also lines at the foot of south walls, may be planted at once—that is, if the state of the weather permits. Select short-topped, early maturing varieties for this early planting, giving the preference to tubers furnished with the first strong sprout only. Medium to light free working soils are best, and the tubers may be planted 8 inches apart in drills 20 inches asunder. Unless the top growth is protected from frosts, first with a ridge of soil, and later with mats, blinds, branches of evergreens, or anything else suitable, the crops will be light.

Sowing Onions.—Raising a few or many plants under glass, duly hardening and planting out, is the surest way of having large well-matured Onions, either for exhibition or for storing. Any of the White Spanish type are suitable for the purpose, giving the preference to the extra fine show sorts if prizes are desired. Sow the seeds thinly in boxes of fine moderately rich soil, and place in gentle heat to germinate. Keep the young plants sturdy by exposing them to light and sunshine, hardening them sufficiently for planting in the open ground early in April.

Large Leeks.—If these are wanted for exhibition in August or September sow seed of a large variety, and treat exactly as advised in the case of Onions. Plants obtained in this way are not liable to run to seed prematurely, whereas autumn-raised plants are given to "bolting."

Early Celery.—Late in January or early in February is a good time to sow seed with a view to having extra early "sticks," but it must be remembered that these plants are liable to bolt in the autumn. Not much seed should therefore be sown now, more reliance being placed on plants raised a month or six weeks later. The white-stalked varieties are the best for present sowing, as these can be blanched ready for use more quickly than the pink or red-stalked sorts. Sow seeds nearly or quite on the surface of pans of fine soil, place in a brisk moist heat, cover with squares of glass, shade heavily, and keep the soil uniformly moist till the seed germinates, when the shading should be removed and the seedlings gradually mured to the light and air. A shelf near to the glass is a good place for them preparatory to pricking out in boxes.

LARGE HIVES.

"A Promise Fulfilled," by "G. H." (page 70) has been a long time coming, and is unsatisfactory to bee-keepers who advocate and use large hives. Before proceeding further on the subject it may be of interest to refer back, with a view to ascertaining what "G. H." has previously said relative to this subject. At first he showed commendable anxiety for the bees, and propounded an exercise in arithmetic as to the number of eggs a queen would lay in a day if provided with a given number of frames. The next was the amount of honey to be obtained; 250 lbs. was to be taken as a surplus, and 100 lbs. left in the hive for stores. In theory this was a great success, but in practice it would not stand the search light being turned on.

In connection with the former he says, "On March 3rd one of our members stated that day he had examined one of his hives which has twelve frames, 18 inches by 9 deep; the bees covered nine frames, and he observed several drones." Referring again to this stock, "G. H." says, "I should think by the end of April or the first week in May the bees will crowd the hive." I then asked him a question which he has not answered—namely, if according to his own showing a queen would lay from 3000 to 4000 eggs per day, what had become of the bees? On March 3rd the bees covered nine frames, whereas by the first week in May they only covered twelve frames.

From the former date to the latter is eight weeks; 3500 eggs laid daily would amount to 196,000. Perhaps "G. H." will inform your readers what had become of the bees from this wonderful colony. Working on the same lines it would take several of his twelve-frame hives to hold the bees from that one stock by the time of the honey flow at the end of June.

In a subsequent note about the 350 lbs. of honey from one hive, "A Border Bee-keeper," who could vouch for the truth of the statement he made, that the above weight of honey "was not taken from a single hive, but was taken off in a week by the owner of an apiary of some twenty hives, who suffered the statement to be spread abroad unchecked;" such are the facts as they have appeared.

LARGE YIELD OF HONEY.

Referring to "G. H.'s" remarks, page 70, he mentions the fact of 334 lbs. of honey being taken from one stock of bees during the past season in the Isle of Man. This has been adverted to in several papers for some months past, and from information received from a neighbouring bee-keeper, who was an eye-witness of what was being done in Mr. Quayle's apiary, and his description of the bee forage in that particular district, I have no doubt the above figures are perfectly correct.

But what was the cause of this record yield? In the first place the colony of bees under notice did not swarm. The weather, that all-important factor in honey production, was more favourable throughout the season than from any other part of the kingdom from which I have received a report. The bee forage was exceptional; and that particular part of the Island must be looked on as a perfect paradise for bees. First came the White Clover, which was in good condition for honey production, not having suffered from the drought as in many parts of the country. Before the White Clover was well over there was a wide expanse of wild herbs, chiefly wild Sage (so it

is called on the Island) in the immediate neighbourhood of the apiary. On this the bees worked freely and stored an abundant surplus. Yet another harvest was in store from the Heather, and when we take into consideration the glorious weather that prevailed the whole of the time, as it was in bloom earlier there than in the northern counties of this country, we cease to wonder how the above large surplus was obtained.

Such a large yield of honey could only be obtained under exceptional circumstances, and shows what may be done under good management when there are three distinct harvests and the weather is favourable. It is not possible for a single colony of bees to store a surplus approaching the above from one source.

STANDARD FRAMES.

The size of the standard frame is 14 by 8½ inches, while "G. H." recommends a frame 20 by 8½ inches. Does he think that a few inches difference in the length of the frame, either one way or the other, makes any material difference in the hands of a practical bee keeper in the amount of honey that is stored? My experience is that it does not. Bees would work as freely and store as good a sample of honey in frames 28 inches in length as they would in those 8 inches or 14 inches less.

But whatever sized frame a bee-keeper starts with, I would strongly advise him to keep to it, as it simplifies matters considerably if all frames are interchangeable. If experiments are to be tried restrict them to a limited number of stocks, and let the bulk of them be of a recognised size. The standard frame is now extensively used throughout the country, and before condemning it in favour of another size, it is as well if we study the question and see where the difference is.

This, I venture to say, "G. H." has not done, as he recommends a hive holding twelve frames 20 by 8½ inches; this he classes a large hive, but which is really much smaller, as I will endeavour to show, than the standard frame hive as advocated in these pages. Many times I have stated the size of the hive I favour—namely, the body hive containing ten standard frames. Another hive the same size placed on the top, which may be termed a super, holding nine frames of the same size. The reason there is one frame less in the super is to allow the frames to be placed wider apart, so that the bees will make deeper cells for storing their honey. Now, nineteen frames, 14 by 8½ inches, gives 4522 inches of surface. Twelve frames, 20 by 8½ inches, gives 4080 of surface, a difference in favour of the former of 442 inches of storage room.

This should convince "G. H." that he doubtless unknowingly has been recommending a smaller hive than the one he condemned. It would have been more satisfactory if he had given the average of the twenty hives experimented on instead of the weight of surplus obtained from one.

If "A Yorkshire Man" should accept his invitation to inspect his apiary next June, he will doubtless have something interesting to give your readers. I do not despair of claiming "G. H." a disciple of the doubling system, and if he will give it a fair trial without bias, he will not be disappointed at the result.—AN ENGLISH BEE-KEEPER.

LARGE FRAMES.

Will George Howdenschire kindly inform one who is just commencing bee-keeping where to obtain the frames he mentions on page 70, 20 inches by 8½, also the size hive he would most recommend? An early reply will oblige, as I am starting on my house to hold six or eight hives, and I may have to alter the dimensions.—WARWICK.

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8, Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Superphosphate for Lawns (R. L.).—In the case mentioned, what was regarded as a drastic application was resorted to in the absence of the family for some time. The dressing was equal to 5 ozs. to the square yard, given early in March. Bright dry weather followed, the moss was dried up, the surface left bare and brown for a time, but soon assumed a green hue, resulting in a close sward of fine grass in lieu of the moss departed. A simple, safe, and good lawn and pasture renovator, used by the late Dr. Hogg, consisted of 5 cwt. of superphosphate of lime and 1 cwt. of sulphate of ammonia per acre, applied in February or early March, according to the weather.

Gall (Burr) on Cob-nut Growth (W. P.).—The growth is simply a burr, common in some districts on Hazel, and used by schoolboys for "hockey" games. The origin of these growths, common to Beech and Elm as well as Nut trees, has been attributed to various causes. In the present instance it is fungoid, with the tree in the ascendant in the matter of resistance. We have not seen the "fruit" of the fungus, which is a nectria. Its action is clearly defined in the burr, following the annular layers of wood, and has broken through the bark. Removing the burr (it is not a gall) is the only remedy. The burrs are very interesting as showing alteration of parts due to parasitic influence. Excrecences are also caused by mites and weevils.

Insects on Roots of Orchids, Eucharis, and Ferns (J. L.).—The "insects" are myriapods, distinguished from true insects by there being no clear mark of distinction between thorax and abdomen, composed of many segments, legs numerous, always more than eight, hence readily defined from the spiders. The specimens are very fine examples of the earth snake millipede (*Julus terrestris*), and are general feeders, consuming both decaying and living vegetable substances, and, on a pinch, prey upon slugs, insects and their larvæ, pupæ, and earthworms. In particular, they feed upon Carrots and Potatoes, but various other plants are seriously injured by their attacking the roots, especially those of Orchids, Eucharis, and others of a fleshy character. The best baits are those you have been using—namely, Carrots, Mangolds, Turnips, and Potatoes, and there is no safer means of getting rid of the pests.

Roses Under Glass (Roses).—We presume you are securing the growths to wires a foot or so from the roof of the house. Some of the finest blooms of *Maréchal Niel* that we have seen in the greatest numbers were produced by strong young stems trained about 6 inches apart in the growing season and there left to produce their golden harvest. It does not in the least follow if the growths of your Roses have not been made under the best conditions in the summer that they will bloom satisfactorily in the spring under any particular distances of training now. The most successful growers of *Maréchal Niel* and other climbing Roses under glass cut the stems down to the base of the rafters soon after the flowers are cut, and run up fresh young growths to the top of the house for producing the next season's supply, and so on from year to year. Roses pay the best between October and March if the crops of flowers are good. If you have the back numbers of the *Journal of Horticulture*, on pages 388 and 430, October 21st and November 4th, 1897, you will find useful information. If you do not possess those numbers send 7d. in stamps to the publisher, 12, Mitre Court Chambers, Fleet Street, London, E.C., and ask him to post them to you. For a good little shilling book on Roses in pots write to Mr. William Paul, Waltham Cross, Herts. If you send stamps add 2d. for postage. We do not remember the London publishers. Though it may not contain all you require you may gather from it much that may be of service.

Soil for Vines Infested with Fungus (T. W. M.).—The fungus is the very distinct *Psilocybe* (*Agaricus*) *conofaciens*, readily known by the dark colour of the pileus and stem, both of which are sprinkled with white fibrils. It is inodorous, and not edible. So far as we know it is wholly saprophytic (living on dead matter), and generally springs from rotten straw or the dead parts in or on the soil of gramineous plants. There does not appear to be any reason to suspect it of destroying living roots. We should apply a dressing of air-slaked best chalk lime, using 1½ lb. per square yard, and pointing in lightly. This will tend to reduce the organic matter and convert it into food for the Vines instead of for feeding toadstools.

Rusty Spots on Chrysanthemum Leaves (Joseph Leach).—The leaves are infested by the *Chrysanthemum* leaf-rust fungus (*Uredo chrysanthemi*), which first appeared in this country last year, and has been figured in our columns fig. 57, last vol. You have done quite right in isolating the 300 plants, and instead of using flowers of sulphur you should apply a fungicide containing sulphate of copper, such as anti-blight, lostite, or other advertised kinds, dusting the under side of the leaves most, but also on the upper surface, as there are pustules of the parasite there. The fungus is very malignant in its action, and must be promptly destroyed, it having now reached Yorkshire, and evidently means business. If you prefer a liquid application use sulphide of potassium, ½ oz. to a gallon of water. Act without delay, for the pest passes very rapidly from leaf to leaf and plant to plant.

Gooseberries for Cordons (Worplesdon).—All varieties are not equally suitable for this easy, ornamental, and productive method of producing Gooseberries. As visitors to the meetings of the Royal Horticultural Society know, Messrs. Veitch & Sons have exhibited splendid samples of these cordons densely clothed with fruit. Among the best of these were Clayton, Dan's Mistake, Eskender Bey, Slaughterman, Criterion, Lord Raneliffe, Mount Pleasant, Pretty Boy, Railway, Fearless, Jenny Lind, King of Trumps, Queen of Trumps, Snowball, Bright Venus, Broom Girl, Early Red Hairy, Ironmonger, Red Warrington, and Whitesmith. The last six named are usually regarded as dessert varieties. In the *Journal of Horticulture* of August 19th, 1897 (page 165), an illustration is given of cordon Gooseberries as they appeared three years after planting in Mrs. Chrystie's garden at Bookham. The wire fence to which they are trained is 5 feet high, and for that height the following varieties proved the most satisfactory:—Hepburn's Prizetaker, Green Laurel, Rifeman, May Duke, Whinham's Industry, White Captain, Whitesmith, Red Champagne, Early Sulphur, and Dan's Mistake. Two tall growers, Highlander and Lomas' Victory, did not spur well. Medium growers and free bearers suitable for a trellis 3 or 4 feet high were found in Early Kent, Early Green Hairy, Surprise, Railway, Goblin, Syon, Leveller, Mount Pleasant, Fearless, Bright Venus, and Forester, the six last named being rather shorter than the others. The land was trenched and well enriched. In the summer a mulching of half-decayed manure spread on the soil on the south side of the row, which runs east and west, proved very beneficial. Copious supplies of liquid manure are given when the fruit is green and swelling, and also after it is gathered, to enable the spurs to produce bold fruit buds. This is excellent practice in the case of all fruit trees and bushes which have been more or less exhausted by heavy crops of fruit.

White Jerusalem Artichoke Attacked by Mould (A. B.).—The tubers are quite "eaten up," black and rotten inside, and smothered externally with a dense white mould, amongst which appear here and there black bodies, ranging in size from a pinhead to a pea, and even larger. There are not two funguses, as you suppose, for the mould is simply the densely felted mycelial hyphæ or threads, entirely devoid of fructification, this being commonly suppressed in both the attacks on the Jerusalem Artichoke, Potato, and Tomato, and is unquestionably the worst of all parasites infesting these plants, as its sclerotia (the black bodies) may live in the soil for years before producing the ascophores, which mean danger of infestation over a prolonged period. The black lumps are the resting stage of the fungus, and from these spring, generally in the early summer, small Mushroom-like growths, bearing on their discs the asci or spore cases containing the spores, which in due course are discharged from their apices, and borne by the wind or other agencies over wide areas. The White Jerusalem Artichoke is particularly liable to be attacked by the fungus called (in the mature state) *Sclerotinia sclerotiorum*. We have received a fine specimen from Kent, and now yours from the North Riding of Yorkshire shows the disease or fungus to follow or be introduced with the host. It, however, attacks the old Jerusalem Artichoke, but not to nearly the same extent, the albino form being tenderer than the coloured. The remedy is to burn all the infested plants and not grow Artichokes, Potatoes, or Tomatoes, or even any *Compositæ* member, for it grows on Sunflowers, on the land for some years. The best dressing for the land is quicklime, using 10 tons per acre, 1½ cwt. per rod, just slaking freshly burned best chalk lime so as to cause the lumps to fall into a fine powder for ready distribution, spreading whilst hot, and in the course of a few days pointing in with a fork. To disinfect tubers, use corrosive sublimate, finely powdered, 1 oz. dissolved in a gallon of hot water overnight in a wooden vessel, and dilute to 6½ gallons, letting it stand for five or six hours, stirring two or three times to secure an even solution, then immerse the sets for half an hour. The sets must only be used for planting, as the corrosive sublimate solution is a terrible poison, and must be used with extreme care. We have found this procedure answer, care being taken to select apparently sound sets. We ask you to be very careful with the corrosive sublimate solution, though it will not harm anything but the fungus at the strength named unless taken into the stomach. It corrodes metal vessels.

Cockchafer Grub (C. C. H.).—The specimen sent is the grub of the cockchafer (*Melolontha vulgaris*), that feeds on the roots of various shrubs and trees for about three years, when it becomes pupa, from which it emerges in the spring in perfect form—the familiar May bug or cockchafer. The larva is very destructive of tender roots and partial to vegetable matter, such as that of the decayed parts of manure and the roots of grasses, and the perfect insects feed on a great variety of trees, sometimes wholly denuding Hawthorn, Hazel, Elm, and Willow of foliage. It also attacks Oaks, and a great variety of other trees and shrubs. The grubs are stupefied, if not destroyed, by a dressing of nitrate of soda, $1\frac{3}{4}$ lb. being used per rod, it being best applied after the ground has been dug level, so that the nitrate gets washed into the soil evenly. It is best applied in the late winter or early spring, alike for acting on the grub and benefiting the land as manure. Soot, at the rate of 1 peck per rod, is also distasteful to the grubs and benefits the plants.

Cocoa-nut Fibre as Plunging Material (P. M. C.).—The sample is cocoa-nut fibre from the mat manufacturers, not the dust or fibre refuse commonly used for plunging purposes. We have used it since 1860, and found excellent in most cases. We agree with you in its being superior to either leaves or tan bark as a plunging material for *Amaryllises*, to which water should be supplied very sparingly until the flower scapes show, and then more freely. Danger lies in overwatering. The rooting of the plants from the bottom and over the rims of the pots into the fibre is the secret of fine leafage and a large storage of matter in the bulbs, only the growth must be ripened by judiciously reducing the watering, and eventually drying off completely. *Hippeastrums* so treated far excel those on which foliage has been retained. The ordinary cocoa-nut refuse—the dust or sawdust-like material resulting in separating the fibre from the husk—is, however, the article commonly used for plunging purposes, and quite different from the hair-like fibre which you use in being lighter, and holding less water.

Insects on Celery (B. G.).—The insects are *Collembola* ("spring tails"), but this particular one does not "jump." It is *Lipura fimetaria*, very common in damp earth, and feeds on decaying or even living vegetable matter, such as Carrots, Celery, Potatoes, or other roots; but the animals are rather the consequence than cause of decay, especially in this case, as the real agent that had been at work was the maggot of the Celery-stem fly (*Piophilus apii*). This pest burrows in the Celery leaf stalks, and causes decay. There are some pupæ in the stems as well as maggots, therefore it would be desirable to burn all infested parts, and dress the land with gas lime to kill any pests left in the soil, using 5 stones of the lime per rod, freshly had from gasworks, and leaving it on the surface for a few weeks before turning under. If that be unattainable use kainit, 7 lbs. per rod, after clearing away the crop and levelling or digging, letting the rains wash it in. Spraying with paraffin oil is the best preventive of attack, using very moderately when the plants are established after planting out, repeating occasionally.

Measuring Timber (W. M. G.).—The contents of a tree "can be got by multiplying the quarter girth by the length" by simple multiplication if you go to work properly. You multiply feet by inches, giving as an example "a tree 20 feet long and 6 inches quarter girth, $20 \times 6 = 120$, and you ask what is the 120?" Then you say "no other true way can be given." Please bring the 20 feet into inches, multiply by the 6 inches, and divide by the inches in a cubic foot, then you will find the contents in a woodman-like manner. But the woodman would not go so far about in the case of round numbers. Your next example is even worse: "Suppose a tree to be 36 feet long and the circumference 6 feet. You will take the quarter of 6 feet, which will be 18 inches, and multiply the quarter girth so— $18 \times 18 = 324 \times 36$ feet = 11,664; divide by 12 and $12 = 81$ feet." That shows a strange way of using the multiplication table. Our way would be to multiply the length by the quarter girth, or 36 feet by $1\frac{1}{2}$ foot = 54 feet, or for keeping our school work in exercise, bring the length into inches and multiply by the quarter girth in inches, and then divide by the inches in a cubic foot. This is very desirable exercise for a man that aspires to teach others but who has forgotten what the schoolmaster taught him.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (D. Williams).—The Pear has been closely examined by several experts, and the majority are of opinion that it is the Spanish Bon Chrétien. It is described in the "Fruit Manual" as an excellent culinary Pear, with a pleasant brisk flavour and musky aroma. Fruit covered with cinnamon coloured russet, and with a lively red cheek next the sun. Tree a vigorous grower and abundant bearer, succeeding well as a standard on

the free stock. (L. O.).—1, Nouvelle Fulvie; 2, Beurré Rance. (J. M.).—1, Scarlet Nonpareil; 2, Boston Russet; 3, Wyken Pippin. (Inquirer).—Winter Franc Real.

A MODEL.

(Continued from page 565, last vol.)

THE dairy, if properly managed, should be the most profitable section of the home farm, and for two reasons—firstly, the production of milk and butter of good quality is probably the most remunerative thing in connection with agriculture; secondly, as a large proportion of the produce in this case would be consumed at home the middleman's profit would hardly count, for the surplus would easily find a retail market in the neighbourhood.

The breed of cattle to be kept would greatly depend upon the locality and the soil, but as a rule nothing beats a good milking breed of Shorthorns. If you go in for a pedigree choose the Bates, as they are much the best milkers; and when selecting a bull get one from a milking herd. There are plenty of owners now who make milking properties a speciality, and it is to one of these we must go for a bull

if we wish to keep up a profitable dairy herd. Never mind if he is a bit light in the neck and thighs, the daughters of the next generation are what we must keep in mind, and milk-making properties rather than flesh.

To keep four cows in regular milk, and at the same time to rear calves and keep up the stock, at least eight females must be kept for breeding, and to allow for cases of barrenness even ten might not be too many. In such a case the bull calves would be fed and sold as veal, or the farm would soon be overstocked; the heifer calves would be reared and bred from until found to be barren, or not worth keeping for dairy purposes. We will take ten as the number of cows kept in stock, two and a half years old and upwards, and we will suppose that they produce nine calves—five heifers and four bulls. Four cows will be kept for the dairy, four will be engaged in feeding off the four bull calves and rearing the five heifers, the other two will be resting or filling up gaps. The calves up to six months would not be counted, as they would run with their mothers or foster-mothers; there would be five heifers between six months and eighteen months old, and five between eighteen and thirty months.

There would thus be twenty head of cattle not counting calves, and these would be quite as many as the farm would carry. The heifers should commence to calve at twenty-seven to thirty months; those not in calf at two years old would be fed off at once. Of the five heifers due to calve down annually sometimes two might be barren; but in any case the three would be ample to keep up the milking herd. Heifers not showing good milking promise would be sold, either fat to the butcher or in store condition to the grazier. Those promising well would be kept on, drafts from the cows being sold to make room for them when found desirable. If the cows breed regularly it will be most profitable to sell the older ones just before calving, and if managed as we suggest it will not often be found necessary to retain a cow after the fourth calf; she will then be still in her prime, and make a good price. Cows, like horses, should, except in the case of a very exceptionally good animal, be sold before they begin to show signs of age. A farmer should never have either a mare or a cow over the age of seven.

A properly built and well ventilated dairy would be an absolute necessity, and the same might be said as to the cowhouse. Cleanliness to the end is absolutely essential when dealing with milk, and it is no use to have marble slabs and purity in the dairy if the animals are kept and milked in a reeking filth hole. The summer food of milk cattle is the natural one of grass, with the addition of cotton cake. If the land be good and deep, and not subject to drought, nothing else would be needed; but where the land is dry, and of such we have experience, we find it necessary to grow a few Tares to mow green for the cows when the pasture is running off, and the effect is seen in the diminishing supply of milk. A plentiful supply of pure water must be always available both winter and summer, and there must be no mistake about the animals getting as much of it as they care to drink. A cow will soon run dry if she does not have a sufficient supply of water.

Milk cows should be brought up early into the yard in autumn; warmth is a great point, and people are apt to leave their cows out at grass after sharp frost has warned them that summer is past. They may save a little food for a week or two, but it is more than likely that nothing is really gained, and they had much better take the cow by the horns and house her before her supply of milk has sensibly diminished.

A good thing to use if you wish to dry a cow is Barley straw; therefore we should very strongly advise that Barley straw should be reserved for the cart horses, and that Oat straw should be given to the cows. Hay is considered by many to be the staple food for dairy cattle in winter, but hay is expensive, and though a little in mixture may be, and probably is, a good thing, we should not make hay the sheet anchor.

We would prefer to give chaffed hay and Oat straw in equal parts as a foundation with pulped Carrots or Mangolds mixed amongst it. Dried grains, malt culms, and bran, 2 lbs. per day of each, for each

animal, with 5 lbs. per day of cotton cake, should make a good ration of artificial food. The cake would be best given at milking time in the morning, the grains and bran scalded and given at the corresponding period in the afternoon; the culms if mixed with the pulped roots and chaff would encourage the cows to clear out the manger of those particular foods.

WORK ON THE HOME FARM.

The combined mildness and dryness of the present month are testing the memories of our oldest inhabitants. We suppose there has been such January weather before, for did not Solomon say that there was nothing new under the sun? but no one living appears able to remember such a winter.

We have not yet seen a drill at work, but so many farmers are talking of making a commencement, that with a continuation of present weather, the sowing of Lent corn will no doubt soon be in actual progress. With such a dry tilth, no doubt such is a wise procedure on all soils of more than medium richness and condition; but on light land, or low-lying and badly drained soils, we should advise caution, for we have seen March winds make sad havoc of early Oats and Barley on such land. Spring Wheat, on the contrary, may be sown now onwards until the end of February; but, having had considerable experience with spring Wheat, we should not recommend sowing later than that. White Wheats, such as Hunter's, Stanhope, or Cole Ambrose, are the most successful for February sowing.

Stock generally are doing well, and keeping is now very plentiful. Turnips are, however, beginning to run to seed, and will deteriorate rapidly, unless we have frost to check them.

Laubing has not commenced yet, but the ewes are healthy, abortion very rare, and the outlook of the season is very promising.

A week ago we were busy sorting and delivering Potatoes at satisfactory prices; since then, foreign supplies have put a damper on the trade, and buyers hold aloof. We have not so many left as to make us in the least anxious as to be in a hurry. It is a long cry to midsummer, and the German supplies are, we hear, very limited.

The horses have been well employed working fallows, and one field is so clean and satisfactory that we shall take a crop of Barley instead of Turnips. 3 cwt. of slag and 2 cwt. of kainit per acre will be sown at once, and the seed drilled in March.

The labourers have been kept busy at the fences, which, in another fortnight, will be completed for the season.

REMARKS.

- 16th.—Overcast and dull throughout.
17th.—Fog almost all day, thick till 10 A.M.; sun visible after, and bright for a little while at 1 P.M.
18th.—Mild and fine, with intervals of bright sunshine.
19th.—Fine, but sunless.
20th.—Damp and rainy almost throughout.
21st.—Very mild; damp and rainy till 10 A.M., fine after, with faint sun from 11 A.M.
22nd.—Bright sun all morning, fair afternoon, and fine night.
Barometric pressure and air temperature very high; rainfall very slight.
23rd.—Dense fog early, and more or less fog almost throughout.
24th.—Fair, but sunless.
25th.—Overcast all day.
26th.—Overcast throughout.
27th.—Fair, but sunless.
28th.—Fair, but sunless.

BARR'S SELECT LIST OF THE BEST PEAS.

LIGHTNING, the best first early round-seeded Pea: pods well filled with good-sized peas of fine flavour; free cropper. Per quart, 1/9.

PRIDE OF THE MARKET, a fine second-early round-seeded Pea; a great cropper, covered with large well-filled pods of deep green peas. Per quart, 2/-.

GRADUS, the best early MARROWFAT; pods large and handsome; peas of rich flavour. Per quart, 3/6.

TELEPHONE, a grand exhibition MARROWFAT, bearing in great abundance long, handsome, broad pods well filled with large peas of delicious flavour. Per quart, 1/6.

DUKE OF ALBANY, a fine main-crop MARROWFAT; large, handsome, and of rich delicate flavour; a grand exhibition Pea. Per quart, 2/6.

NE PLUS ULTRA, SELECTED STOCK; a grand late Pea, unsurpassed for flavour; pods large and abundantly produced; an extra fine stock. Per quart, 1/9.

BARR'S SEED GUIDE contains a Select List of the best Vegetable Seeds and most beautiful Flower Seeds. It is full of Practical Hints, and will be found of great value to Gardeners, Amateurs, and Exhibitors. SENT FREE ON APPLICATION.

SEED LIST.

(FREE ON APPLICATION.)

FEATURES.

Alphabetically arranged.
Best sorts in heavy type, can be seen at a glance.
Probably the most explicit practical instructions for cultivation ever published.

Many hints and recipes for cooking and serving the various vegetables.

Directions for the storing and forcing of vegetables.

Medicinal qualities of many vegetables and herbs.

PRIZES of £5, £3, (two of) £2, and £1 offered for PHOTOGRAPHS of HORTICULTURAL SUBJECTS. (See page 2 of Catalogue.)

THE LIST

Containing 93 pages, and a profusion of illustrations, shows—(a) WHAT TO GROW; (b) HOW TO GROW IT; and (c) WHAT TO DO WITH IT WHEN GROWN; and has been described by an Agent on one of the largest estates in England as a BOOK OF REFERENCE.

Another Customer, testifying as to quality, writes:—"I should like to add that all the seeds, &c., purchased from your Establishment during the past fourteen years have been of the very best quality, and have given the greatest satisfaction."

CINERARIA AND CELERY PESTS.

THESE have been alluded to by Mr. G. Dyke in his interesting notes on page 56, January 20th. The term "pests" implies more than one, hence the "leaf-miner, or larvæ of the Celery fly (*Tephritis onopordinis*)" must mean something different from that which effects the "mole-like burrowing in the leaves" of Cinerarias.

The Celery fly belongs to the family Tryptetidae of the order Diptera (two-winged flies), and infests (by its small, fleshy, legless white maggots) the leafage of Celery, Parsnip, and other umbelliferous plants, producing at first whitish blisters on the leaflets, afterwards brown in the destroyed parts, greatly disfiguring and sometimes ruining the crops. It may or may not attack Cinerarias, and thus another question arises—namely, identity of species, for I do not know the Celery fly as a pest of Cinerarias, but have plenty of experience with the ruinous Marguerite leaf-blisters fly (*Tephritis artemisæ*), which also sometimes infests the leaves of our autumn Chrysanthemums, and possibly those of Cinerarias. So far as I know its attacks are confined to the Compositæ, and appear the most malignant on Marguerites.

The best preventive of either of the *Tephritis* is to catch the flies by inserting small sticks in the pots just long enough to reach clear of the plants' foliage, some sideways, and some over the plants, and in a slit at the top of each stick introduce a piece of cardboard about the size of an exhibition plant label card, smearing it on both sides with myocum fly gum. This answers at all times under glass, and outdoors in summer for Celery fly, having the traps just clear of the leafage along the trenches, touching up the "rests" every now and then to keep them in working order. Bits of tin answer even better, as they shine, even when covered with a smear made of resin and sweet oil, in equal parts or thereabouts, melted together.

Against attacks of these leaf-blisters flies, soluble petroleum answers well sprayed on the plants, preferably before, or at least on the first faint signs of infection, using the preparation at the rate of a wineglassful to a gallon of water.

No. 2576.—VOL. XCVIII., OLD SERIES.

This prevents the flies depositing eggs in the leaves, or kills the maggots that may be in the blisters, and only needs occasional renewal to prevent or make an end of the pests. Soluble petroleum does not blister the leafage nor injure roots, but kills the pests and rapidly decays in the soil. Raw paraffin oil does harm to foliage and proves injurious to roots.

The caterpillar of the Cineraria leaf-miner moth (*Nepticula argentella*) has the gift of "mole-like burrowing in the leaves," producing a white or yellowish line or mark, sometimes with purplish margins, and goes somewhat roundabout in curves, but always forward from a starting point, ending at the leaf margin, or where the exit takes place for changing into pupa, and from this emerging as a moth. This belongs to the Nepticulidæ (pigmy moths), and has a near relation in the Bramble leaf-miner moth (*Nepticula aurella*). Beyond the white marking on the surface of the leaf the tunnelling does not greatly prejudice the growth, unless it interfere with the veins, then collapse may ensue. The tunnelling, however, is an eyesore that warrants prevention and remedy.

For the leaf-miner moth I know of nothing better than catching it on smeared cardboard, as previously advised. For the caterpillar crushing between the fingers answers well, only do not squeeze too tightly so as to injure the leaf. The almost legless creature is always situated at the forward end of the mine, therefore nip these early, and further mischief will be prevented.

As for attacks of leaf-blisters or leaf-miner moth being influenced by "the constant use of organic manure," I may say that the softer the leafage the easier it falls a prey to its enemy, and the more solidified the foliage the better it resists blister fly and leaf-miner moth in puncturing. The leaf-miner moth has always been the most prevalent with me when the Cinerarias were fed with stable and cowhouse drainings, and the leaf-blisters the most destructive when nitrogenic manure was liberally supplied. Of course, there are so-called inorganic and organic fertilisers, and even stable and cowhouse drainings are a very uncertain article. In another communication I will refer to flued garden walls.—G. ABBEY.

EARLY POTATOES.

To be able to dig a nice dish of Potatoes a few days earlier than their neighbours is one of the little ambitions of a gardener's life. It is not, however, wise to begin to dig until we have a sufficient stock ready to form a successional supply. Warm borders are not too plentiful in many gardens, and as so many crops are required as early as possible, no great amount of such space can be devoted to Potatoes; yet if only a small patch is planted the supply is not large enough to carry us on till the time when Potatoes grown in open quarters are ready for lifting.

The difficulty may, however, generally be overcome by planting tubers of the short-topped varieties in rough pits. Such pits may easily be formed by placing soil in ridges shaped into the form of a range of pits. The ridges need not be more than 2 feet in height at the back and 15 inches in the front. Rough frames made of boards will do almost as well, but they have this drawback, that if we happen to get a severe frost after the Potatoes are up, a great deal of protecting material needs placing round the sides, as well as over the top of the pit to keep out frost, whereas a pit formed with earth sides can be depended upon to keep the Potato tops uninjured, if the top of the frame is well protected. I like to make the soil in these pits thoroughly light and rich, as I find they seldom require water more than once, and a soil in which the young tubers can work freely facilitates their growth. When digging the pits, therefore, work in a large quantity of thoroughly decayed old hotbed manure, mixed with the soil of the hotbed. Although fresh manure should never be largely given to soil in which Potatoes are to be planted, when thoroughly decayed it may with advantage be used. When planting in the limited amount of space afforded by pits, it is necessary to turn it to the best advantage. Short topped varieties such as Sharpe's Victor I plant a foot apart each way, instead of giving a greater distance between the rows, as when they are grown in the open air. In pits, of course, we place soil over the whole surface instead of forming it into ridges, hence the difference in the method of planting.

For planting choose medium-sized tubers, previously prepared by being sprouted in boxes, or started in small pots, not more than two shoots of course being left on them. If planted from pots a trowel should be used for the purpose, but when the tubers have

been simply sprouted in boxes the dibble answers well; in either case cover the tubers with 3 inches of soil. After planting, any old lights at command should be utilised for covering the pit. The only attention required till the sprouts push through the soil is to cover at night, or at other times when the weather is severe, and to remove the covering in bright weather, so that the sun may warm the soil. As growth takes place air must be given on favourable occasions, and 3 or 4 inches of soil placed between the plants when they are about 6 inches in height.

Turning to the culture of early Potatoes in the open air, it is well to note that very early planting is not to be commended, unless means are taken to protect the tops from sudden frosts; but given a warm position in front of a wall facing south, and the necessary attention in regard to protection, tubers fit to dig may be obtained fully a fortnight earlier than from the open ground where they have received no protection. If the present favourable weather continue those who have a warm border should plant a fair breadth during the second week in February, and make another planting two or three weeks later, as by so doing a regular succession can be obtained from the time those in earth pits are dug till those in open quarters are ready. Ground which has been well manured for the previous crop is usually in good condition for Potatoes, without any addition being made, if it is light and in fine working order. In dealing with such a soil I am fully convinced of the advantage of delaying the digging till a day or so before planting takes place; and I also believe that, as a rule, heavy land is greatly benefited by throwing it up roughly in the autumn, so that frost, air, rain, and sunshine may exercise their ameliorating influences upon it. I am aware that there are some very tenacious soils which, if dug in the autumn, are sticky and wet when planting time comes. Such should be left till dry upon the surface, and then be forked over again, for it is the eagerness to get upon autumn-dug land before it is dry in spring that in innumerable instances brings autumn digging into disrepute. Dressing with lime, combined with autumn digging, and the working in of opening materials, will, if persisted in, bring the most stubborn soil into a friable condition. This slight digression will perhaps be pardoned, as it is a matter of great importance, now being discussed in the *Journal of Horticulture*.

In planting early Potatoes in the open air I prefer to set them in drills rather than holes made with the dibber, as the soil around the sets is then left in a condition favourable for the young roots to work in. We have many early short-topped varieties of great merit, these need not be allowed nearly so much space as later ones. From 15 to 18 inches is a good distance to set the rows apart, placing the tubers 10 inches asunder in the rows. As soon as they are an inch above the soil, a sharp look out ought to be kept for frosts; a little soil drawn over the tops answers well for a time, but later on it is necessary to cover with rough straw or similar materials. As the tops are young before being earthed, it is a good plan to fork lightly between the rows, as it allows the warm air to penetrate and thus forward the crop. During showery weather in April a little nitrate of soda scattered between the rows helps to promote rapid growth, as well as to enable the plants to draw largely upon the store of other food present in the soil. When the tops have attained a height of 6 inches earthing should be done, bringing the ridges just up to the tops of the haulm.

Many new varieties have been put upon the market during the last ten years, and some of them have proved decided acquisitions. The one already referred to—Sharpe's Victor—has become a general favourite and is largely grown; but it will, I think, soon be left behind in the race for popularity by a round variety sent out by the same firm—viz., Early Six Weeks. This is, I consider, one of the earliest varieties in commerce, and all should give it a trial. Improved Ashleaf, though not quite so early as some of the newer introductions, has this advantage—viz., that the tubers are always of good quality, even when somewhat undersized, compared with other varieties planted at the same time. It is a pity that Messrs. Sutton & Sons are not able to offer seed of Al this season, as it is one of the good things which everyone is trying to get. Ringleader, sent out by the same firm, is also in the front rank of early sorts. Puritan is a wonderful cropper which produces large tubers, but is scarcely so early as any of those previously named. Dickson's Dwarf-top Ashleaf ripens about the same time as the old Ashleaf, and its dwarf habit of growth is a distinct gain. Britannia, sent out by the same firm, seems to be an exceedingly promising variety. Sutton's Seedling, though scarcely so early as the majority of those named, is good for a succession, and is, I think, the most handsome Potato grown.—H. D.

ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the Society, to be held at the Institution of Civil Engineers, Great George Street, Westminster, on Wednesday, the 16th inst., at 7.30 p.m., the following papers will be read:—"Report on the Phenological Observations for 1897," by Edward Mawley, F.R.Met.Soc., F.R.H.S. "Monthly and Annual Rainfall in the British Empire, 1877 to 1896," by John Hopkinson, F.R.Met.Soc., Assoc.Inst.C.E.

OPEN AIR CULTURE OF MUSHROOMS.

As a grower of Mushrooms in the open air with more or less success for several years past, a few notes on the subject may be of interest to others who are similarly situated, and who, like the writer, have a difficulty in procuring manure for that purpose. We must acknowledge our indebtedness on many occasions to that admirable book, "Mushrooms for the Million," which is as valuable to-day as when first published, and no one who wishes to excel in the cultivation of Mushrooms, whether indoors or in the open air, should be without a copy. There are, however, many things both in the preparation of the manure and in the management of the beds that cannot be learned from a book. Only practice and close observation will make the cultivator an adept in the outdoor cultivation of this esteemed esculent. This is not at all surprising, as the temperature is an important factor, and when one takes into consideration the rapid changes that take place in this country in a few hours it shows the necessity of always being on the alert.

THE BEST SEASON FOR MAKING THE BEDS.

Spring and early autumn is the most suitable time for a beginner to commence. Beds made up in September invariably answer well, as the mean temperature is about 60°. If the beds are covered with a few inches of litter they will remain a few degrees higher than the above for at least a month after being spawned. The mycelium will then have fermented the whole mass. The nights will become cooler, and the temperature of the beds falls a few degrees lower. This will be an advantage, as when the Mushrooms make their appearance, if a thermometer is placed on the surface of the bed and it registers 55°, the Mushrooms will be thick and of good substance, but if the temperature is too high they will be thin and light. There is no comparison between a fleshy, well-grown Mushroom, and one that has been imperfectly matured either by being grown in too great a heat, or when the temperature has been too low.

MISTAKES IN PREPARING THE MANURE.

There are more mistakes made in the preparation of the manure than many cultivators are aware of. There is, however, this consolation, growers often learn more from a failure than they do from success. We must own to some partial failures which at the time could not be accounted for, and the spawn was blamed, whereas we are now convinced the fault lay with ourselves in the preparation of the manure.

Cultivators should bear in mind the fact that the beds made up during early autumn ought to be very moist; the beds, too, must not be spawned at too high a temperature; 70° is quite high enough. At midwinter the manure should be much drier, and may be spawned at 10° higher.

In preparing the manure we only remove the long litter, as this is valuable for covering the beds, and preferred to clean straw. If the manure has been in a heap for several weeks, it will have heated itself quite dry. The whole mass must then be turned and well shaken out and sprinkled with water. This must be repeated as often as necessary. We usually turn our manure every other day. This is done in the open air, and usually takes about three weeks before it is ready for use.

GROWING MUSHROOMS IN LEAVES.

Owing to a scarcity of manure we have for some time been on the look out for a substitute, and have tried several experiments. Leaves being plentiful, and vast quantities having to be cleared away annually, an attempt was made to utilise them in a more profitable manner than burning or rotting them down for manure for the garden. They thus came readily to hand, and were used in conjunction with manure for growing Mushrooms.

At first only one part leaves to three parts horse manure was used; these proportions proved a great success. Since then we have increased the proportion of leaves, so that at the present time we are making up our last beds for the season with only one part manure to three parts leaves. These beds we have little doubt will, in due course, carry heavy crops of firm, weighty Mushrooms. As showing the bulk of leaves that has been used we may state that upwards of sixty cartloads, the carts having specially made deep boards for that purpose, were used during the past two months. We prefer small leaves for that purpose, such as Beech and Oak, and do not use large leaves as Chestnut and Sycamore. These are prepared in the same manner as manure, but do not require turning so many times.

HOW THE BEDS ARE MADE.

For outdoor cultivation of Mushrooms the ridge system is the best, and no advantage is gained by making them too large. They may be made any length, but 2½ feet wide at the bottom, 2½ feet in height, and 6 inches wide at the top when finished off are suitable dimensions. Beds of this size, if properly managed, will retain sufficient heat to

enable the mycelium to run, and eventually grow a heavy crop of Mushrooms.

With a little practice the men soon become adepts at making the beds. They commence by placing a layer of manure on the bottom a foot in thickness; this being trodden firmly, another layer must be added and treated as before. The sides must be well beaten with the back of a fork as the work progresses, the man using it standing on the ridge, otherwise the sides will not be kept true, and when the whole is finished the outline will be true and regular.

The ridges must then be covered with a few inches of litter, this being important at all seasons. It is advisable to keep the litter clear for a couple of inches from the centre of ridge, as this will allow the steam to escape freely.

SPAWNING THE BEDS.

If the manure has been properly prepared, and the beds made in good order, it will be found that the temperature has declined sufficiently to allow of the beds being spawned on the fourth day. The beds should never be spawned until the maximum heat has been reduced and the heat is falling. A thermometer inserted a couple of inches in the bed will probably rise in a few days to 100° or more; after it has fallen to 80° or less it will be safe to insert the spawn.

A cake of spawn is divided into eight parts, and these inserted evenly over the bed about 9 inches apart, slightly covered with the manure, and not buried more than from 1 to 2 inches in depth. After the bed is spawned it is made firm with the back of a fork. It is impossible to make a ridge too firm; but it is a very simple matter to make it too light, when the produce will not be nearly so satisfactory as when the bed has been properly made.

CASING THE BEDS.

We always case our beds with soil directly they are spawned. Some successful growers delay the casing of their outdoor beds until the spawn has commenced running, but, after trying both plans, we did not derive any benefit by following the latter precedent, so the beds are now finished off at once, and it has the advantage of saving labour, besides preventing the heat from escaping during a spell of cold weather such as is often experienced at this season.

The beds are covered with about 2 inches of good soil placed evenly over the surface of the bed, and if dry moisture is added, otherwise there may be a difficulty in placing it in position. A little practice will soon enable one to do the work well. The ridges are at once covered with litter; if the weather is warm, as it often is in the autumn, a few inches will suffice, whereas a foot or more may be necessary in cold weather. The beds are examined occasionally after being spawned to see that the temperature does not rise too high, as the spawn is easily destroyed in its early stages.

MANURE FOR FUTURE USE.

It is not advisable to make up beds (unless in a very cool place) after the first week in March, as by the time the beds come into bearing warm weather may be expected; the Mushrooms will then be of little use, as they will not develop in a high temperature at that season, decay will set in and they will be useless. Manure from this date onwards may be allowed to accumulate in a heap in the open air. It will become dust dry, but will grow good Mushrooms the following autumn if prepared as above directed.—S., *Yorks*.

DIGGING AND TRENCHING.

SPRING *versus* WINTER.

WHEN I penned the few remarks on this subject it was anticipated that, if noticed at all, it might be exactly as Mr. F. Dunn has treated them on page 106. It is pleasing to have from him so emphatic a corroboration of the facts that I wanted to point out. Mr. Dunn writes—"Strong soil such as I have to deal with worked when in a wet state will prove almost unworkable during the following summer." Also, "It is a recognised fact that soil newly dug will retain more moisture than ground which is allowed to remain unbroken." This is exactly what I wanted to convey, and a stronger argument against winter digging or trenching tenacious soils in a wet locality could not be advanced.

It has been my experience of cropping soils from a tenacious yellow clay to others that well merited the description as being heavy, and in one instance where not unfrequently there has been a rainfall of from 50 inches to nearly 6 feet. Invariably I found that seeding and planting could be accomplished far more satisfactorily when the ground was left in a compressed condition till spring, and the cropping done immediately the ground was turned over, and before it got rain. It will surprise me if there are not many gardeners, and farmers too, that will have had this same experience. A well cropped garden should not have much vacant ground in the autumn.

In reference to the law that governs the relative depths to which

frost finds its way into loose and compressed soil (or, to put it more correctly, the radiation of heat in the case of these two conditions), I do not think for a moment that Mr. Dunn would use any body of a solid or compressed character in preference to an open or porous one to prevent the radiation of heat from pits or frames. Neither in a frosty night would he put on a closely woven linen garment in preference to an Irish frieze to prevent the heat leaving his body. The very same law that determines these cases determines the depth to which frost penetrates the earth. The reason why an iron bar conducts heat more rapidly than a wooden one is the same as conducts the heat more rapidly out of solid soil, and lets frost or cold into it, than takes place in loose soil. And you may as well try to alter the law that makes a man stoop when climbing a steep road, and compels him to stand at anything but a right angle from the surface of the incline.

As I have already remarked, the well recognised circumstance that, to prevent the summer sun from sending its heat down into the ground, causing the more rapid evaporation of moisture from the roots of crops, the proper thing to do is to keep the surface constantly in a loose porous state; either this, or to mulch with some loose manure or litter. If the surface be left in a caked or compressed condition you have a medium fitted by natural law to convey the moisture far more rapidly out of the ground, and, moreover, exclude the air from exerting its food-preparing power in the soil. It is impossible to reverse this law's action, and it accounts for what I have over and over again found, the fact that compressed soil radiates the heat out of the ground in winter just as it conducts the heat of the sun into the ground in summer. Mr. Dunn's reference to a piece or lump of soil lying on the surface of the ground and one buried a foot deep in it proves nothing for or against the depth to which frost penetrates under the two conditions in question. It seems to me to point to a mere surface pulverisation.

It might be further remarked that the amount of air in a soil has much to do with the penetration of frost. The more air the more frost-resisting power, hence it is found that a comparatively thin covering of earth keeps the frost out of our Potato pits, provided there is laid carefully next to the Potatoes a layer of straw, with its hollow tubes or stems full of air. This same holds good in the keeping of frost out of glass pits or frames. Lay the mats, or whatever the covering may be, closely on the glass, and the heat radiates far more quickly than if kept an inch or two off the glass, leaving a vacuum for a stratum of air. I have seen damage done to cold water pipes in a hard gravel walk, while not one was broken or burst by frost in the same depth of loose garden soil. For the same reason a wooden shanty is warmer in winter and cooler in summer than one of sheet iron; but the illustration of the working of this law is endless, and no power of man can alter it.—D. THOMSON.

THE PHILOSOPHER IN THE TRENCH.

In the trench? Why, yes! and if you will believe me, prostrate there. But we all respect the philosopher so much that we would fain see him on his feet again. If it be thought that sentence No. 1 here indicates too great a complacency, then perhaps the compliment in No. 2 will balance matters, because Complacency and Compliments have gone together since the world began, and the discreet pages of our Journal give them all the respect which is due to their venerable character.

The beginning of wisdom is often the ending of philosophy. The latter is one of those cheerful things which do useful fair-weather duty, but come to grief under stress of circumstance. As a phrase it has many merits. It possesses resonance and sonority. It bespeaks dignity. When a controversialist lays hands on it common weapons are of little avail. It possesses certain awe-inspiring qualities, so that timid persons are rather afraid to take too close stock of it lest it should go off. When, however, courage is screwed up to the sticking point and examination takes place a flaw is sometimes revealed.

But if philosophy is formidable in itself alone, what are we to think of it in the hands of a past master in the art of gardening like Mr. D. Thomson? Doubt then becomes almost treasonable, as leagued with Presumption. This is a combination so formidable as to give pause to any critic who does not enjoy the twin distinction of professional eminence and ripe years. So he hesitates. It is not, you understand, a thwack from the philosophic flail which he fears so much as the keener barb of seeming disrespect. The new idea likes to assert itself, yet claims the saving grace of modesty. There is but one way out of the dilemma, and that is to remember that conscious strength feels pleasure rather than anger in perceiving that youth is trying to feel its devious way to wisdom.

I read the article of Mr. Thomson with so much interest that when I had finished it I read it again. It was that lurking philosophy which tempted me. I feared it, but still it lured me on. Mr. Thomson's philosophy is that winter digging and trenching is not so good as spring work. Not a very startling thesis, you will say;

indeed, rather an old friend, but put forward so weightily and with so much brainful resource behind it as to almost command the attention of something entirely new. Like a wise general our venerable teacher throws up two lines of entrenchments, one of which consists of philosophic deduction, the other of practical example. On reflection it seems to me that only the latter of these is of much defensive value; as for the other, why it confounds its own designer, and instead of leaving him triumphant on the edge of the trench throws him prostrate in it.

"A loose porous body of material holds more water than one that is solid and compact." The assertion is Mr. Thomson's, and it is indubitably correct. He bases his argument upon it, but goes, as it seems to me, astray in his deductions. It is because of the fact herewith stated that the grand old gardener would leave stiff soil alone till the spring; it is because of the self-same fact that I would attack it in winter. Mr. Thomson goes to natural philosophy for his deductions, and I will follow him there. Is it not a fact that water at freezing point expands? Undoubtedly; what then? Why this, that the greater the amount of moisture within the soil the greater must be the disintegrating action of frost. Natural laws, says Mr. Thomson, are inexorable; but when he goes on to say that "they act powerfully in producing results that tell against the recommendation of the winter tillage of heavy soils in wet districts" I beg respectfully to suggest that he has allowed himself to be misled.

All our excellent friend's arguments, all his "philosophy," would come out right side up if there were no such thing as winter frost; with it they are turned topsy-turvy. Take a piece of strong adhesive clay, such as most horticulturists, old and young, have had to deal with some time or other in their lives (not less often, perhaps, because they are not for ever crying their practical experience from the housetops). The thoughtless man will worry this soil about at much expense of manual labour; the wiser one will let Nature do it for him. Throw it up in December, and what happens? In nine seasons out of ten it gets well saturated with the rains of early winter, taking up, as Mr. Thomson truly tells us, more water than if left packed. The greater amount which it holds the greater will be the natural crumbling or disintegration from the action of the following frosts, which rarely fail to do their work. Note that I say "December" digging. It is an important stipulation. I have seen stiff land dug early in November, and the surface became greasy from the long delay of frost action. This surface grease clogs the soil, excludes the air, and to a certain extent the frost. Perhaps I should not be very wide of the mark if I suggested that Mr. Thomson has observed this soil paste, and been driven by it to the other extreme—spring digging.

But if, as I contend is the case from the law he himself proclaims, winter digging is theoretically sound, it is not less so practically. I should be surprised if hundreds of instances of its benefits could not be quoted. Staggered by the weight of Mr. Thomson's name, not a few worthy workers may doubt the evidence of their own experience, but when they have had time for calm reflection and a quiet look round they will view the matter as I do. I venture to refer to one instance as a set-off to the case quoted by Mr. Thomson.

A particularly vicious example of the London clay in a Kentish suburb had for years set at defiance the hopes of the master, who had been assured by his landscape gardener that if scientifically drained the clay would give abundant crops. Somehow, though, it did nothing of the kind. There was no doubt about the systematic (and expensive) character of the drainage; there was equally none about the poorness of the crops. Then came along an adviser of another sort—one with a very qualified belief in drain-pipes, but a heartily unqualified one in garden forks well wielded—myself. Examination elicited the interesting fact that 3 feet of solid, sour, sticky clay rested on those immaculate drains. It was followed by a prompt inquiry and a prompt answer: "May I do as I think best?" "Yes; go ahead!" Within twenty-four hours a small army of diggers, fork-armed, were at the clay. By mid-December the last rod was ridged. There was rain, there was frost, and, hey, presto! a transformation scene, all brought about by Mother Nature. Crumbly soil instead of sticky lumps, changed in character by frost, greeted eye and hand. By the time Mr. Thomson would have commenced his digging the garden was in kindly working order—the master staring, the scientific drainer rubbing his nose.

If he saw anything that was a lesson to him, and set him thinking, let others follow his example. And now I think of it, I will quakingly rub mine own, in anticipation of Mr. Thomson's return blow.—W. PEA.

EARLY FLOWERS IN SCOTLAND.—I imagine it must be very unusual to see the Hepaticas flower before the Winter Aconite and Snowdrops. May I ask if it is so? Until this season I have no recollection of having noticed this. *Hepatica angulosa* flowered ten days, and the single Pink—blue, white, and double red—a few days before the plants mentioned. If this is the reverse of the usual order, it must, I presume, be due in some way to the very exceptional nature of the season.—SELKIRKSHIRE.

MORE ABOUT SOLUBLE PHENYLE.

How now, "Mr. Editor." There is evidently "something wrong somewhere;" but I think that mysterious something is about solved. Mr. Iggulden is, I believe, a man who practises what he preaches. What does he tell us on page 76? Firstly, that if phenyle be used at the rate of 1 gallon in 1000 gallons of water it will injure foliage, and may be injurious to tender root fibres; and secondly, that he has decided that 1 gallon of phenyle is enough for 2000 gallons of water, and this is the strength it will be used for Tomatoes and Cucumbers this season. I thought perhaps he had made some mistake in his figures, so left my notes over for a week to see if my supposition was right. As no alteration appeared last week, I think we may now take them as correct.

I am under the impression that soluble phenyle has been recommended to be used at the rate of 1 gallon in 96 gallons of water. This was the advice my friends followed, and killed their plants. Now, if Mr. Iggulden thinks 1 gallon of phenyle in 1000 gallons of water will injure tender root fibres, what would be the result of using it ten times stronger? and can anyone wonder at Cucumber plants being killed by using this strong medicine?

I cannot agree with your correspondent as to the manurial value of soluble phenyle. I still think it of no practical value as a fertiliser; but as a little practice with it may clear away these doubts, I will give it a trial before I say anything more on the subject.—W. DYKE.

[An important question remains unanswered. Is the soluble phenyle that some persons find safe and others dangerous to use of uniform quality and strength? We think Mr. Abbey has sent us Tomato roots which have been immersed in the proportions he named, and they were not injured in the least, as could be clearly seen under a powerful microscope. Still, when a weak solution of anything answers, it would be foolish to use a strong one.]

PHRYNIUM VARIEGATUM.

FOR decorative purposes few ornamental foliage plants are more useful than *Phrynium variegatum* (fig. 18). When well grown this plant forms an attractive feature in the stove, and it is also admirably adapted for table decoration. The character of this *Phrynium* is so well depicted in the illustration that a detailed description is unnecessary. It usually grows from a foot to 18 inches in height, and the foliage is prettily marked with deep green. In most cases it is grown in a stove, but an intermediate temperature suits it, and if cultivated under the latter conditions it is hardier and more suitable for the embellishment of warm apartments. We trust this will meet "Decorator's" wishes.

APRICOTS.

THE exhaustive manner in which Mr. Abbey treated the subject of Apricots and their culture would seem to have covered all the controversial ground. The Apricot, however, is so universally accepted as an uncertain and fast becoming an unprofitable crop, that the experience and opinions of others I am sure would form an interesting subject to many Journal readers. That the Apricot has got into bad repute no one can deny, for in so many gardens one hears the same record of partial or total failure through gumming and the sudden collapse of branches, of which Mr. Abbey speaks. In a few gardens they give little trouble—no more, in fact, than Plums, Apples, or Pears.

In his second paragraph (page 31) Mr. Abbey says, "The chief reason of failure in this country is, according to my experience, restriction, the trees never succeeding on low walls, and mentions that on a 10-foot wall he once had a collection of the choicest varieties that in three years dwindled into an unprofitable state, with one exception. Presumably Mr. Abbey would consider 10 feet a low wall, but 2 feet more than this, I think, would cover the height of the majority of garden walls, and there are a few instances where Apricots flourish for many years restricted to this space, while in others, as in Mr. Abbey's case, premature decadence sets in even before they have filled their allotted space. There must be other contributory causes than the limit of space to account for failure, of which there are so many recorded. Natural shelter, soil, drainage, and the stocks on which they are worked account for a good deal, favourably or otherwise. If this is not so, what explanation can be given for trees doing so well in one and so badly in another garden, when root and branch treatment is made a study of by those in charge? I know of trees that are over sixty years of age as healthy and fruitful as anyone could wish, and yet these had obviously filled their spaces years ago, and had no means for farther extension. Here the loss of branches is almost unknown.

Evidently Mr. Abbey is not in sympathy with elaborately prepared borders such as one sometimes hears of as being necessary, for he says, "If well drained, almost any garden soil will grow Apricots to perfection." I have noticed in some cases that where the garden slopes gently or sharply to the south, and there is a belt of trees on the north and north-east sides, Apricots doing better than in other gardens strictly level and without the natural shelter named. Here there was once a wall of more than 100 yards in length devoted to these fruits, which, as in Mr. Abbey's case, was a source of trouble, constant replanting and subsequent dwindling even of young trees. This brought about a resolution with my predecessor to plant no more Apricots, but as they were removed their

places were filled with Pears. There are just a few of the trees still remaining which will not eke out a very long existence; but like the rest, give place to other kinds of fruits. One, however, a standard-trained, seemed to have survived a good many, and there was an absence of the branch decay so common in the dwarf trees.

This, to me, gave rise to the thought that the stock used for standards may be better adapted to our soil than the one employed for dwarf-trained trees: and instead of abandoning Apricot culture as hopeless, I have put in some standards against another south wall in order that I may get some proof of the greater adaptability of the one over the other. So far the evidence is in their favour, but no definite opinions can be formed for some time to come.

I incline to the opinion that in the case of newly planted trees, a frequent and careful digging about their roots, severing any tending

FIG. 18.—PHRYNIUM VARIEGATUM.

towards grossness, and incorporating with the soil in the course of filling in, lime grit, road scrapings—where limestone is used in repairs—leaf mould, and burnt refuse; and although the walls may not be so quickly furnished the trees would be better equipped in having abundant root fibres instead of those of a thong-like description, which usually come from deep and unrestrained growth. To make special borders of turfy maiden soil would be to court failure in gardens so closely associated with gumming, and branch-dying, unless there were a greater depth of wall than is usual in gardens to furnish with the corresponding freedom of growth, which, as Mr. Abbey advises, is better laid in than cut away, so long as undue crowding is avoided.

Of varieties, Henskerk is the best here; this gives large fruit, good in colour and quality, ripening about the middle of August. Kaisha and Moor Park are others that as wall standards are as yet satisfactory. Dwarf-trained trees of all sorts have been a signal failure. Overhead shelter is an invaluable aid to the setting of the crop; where glass coping is unavailable, a wide board is a great help in warding off heavy rains, cold winds and frost.

There is one item connected with Apricots I do not find mentioned by

Mr. Abbey in his interesting articles, and that is the reference to the losses occasioned by woodlice and wasps. After all one's efforts in the production of these luscious fruits, there is often considerable losses from these enemies. Where nailing is resorted to woodlice find abundant shelter, and become more or less in evidence at the ripening period. The best remedy for these, no doubt, would be to close the existing nail holes with a hard-setting composition during the winter months, and where possible to adopt strained wire instead for training. They are not easily trapped when they can find so much shelter in the walls. Wasps are best dealt with at the nest with cyanide of potassium, and Davis' or Scott's destroyers if they persist in sampling the fruit. Squirrels, too, have a strong liking for Apricots, and if once they taste them nothing less than shooting or trapping will stop them; nets are not of the slightest use, they will make passages through them without any exertion. — W. S., *Rood Ashton, Wilts.*

THE N.C.S. PROXY VOTING.

EVERY member of the N.C.S. owes you thanks for the space you have given in its real and permanent interests. Might I ask whether, on so important a matter as practically the future of the Society depends, every member should be allowed to accord a vote? The annual meeting generally takes place in London in the evening, and of course only a very limited number of members can attend. I think a poll should be demanded or proxies allowed.—AN ABSENT MEMBER.

ALL Chrysanthemum lovers will feel thankful to you for affording space in directing attention to the pitiable position of the N.C.S. But while the interest in its condition is on, could not something be done to make it more of a national society by allowing its distant members to take part in the election of officials without the expense of a journey to London? Surely nominations might be made before some fixed date, and then voting papers be sent to members. A thousand halfpenny stamps would about cover the cost, and we should at least feel we had one other privilege beside the privilege of paying our subscriptions.—J. H. SILSBURY, *Hon. Sec. Shanklin Chrysanthemum Society.*

EQUAL PRIZES FOR PREMIER BLOOMS.

I SCARCELY expected to find that another exhibitor could relate a similar instance to that which I referred on page 78; but on opening my Journal of last week I was surprised to find it was so. The Editor requires an explanation from me as to which of the equal best blooms the certificate was awarded. I did not see the Judges after their decision, to inquire the reason for their choice of two blooms, when the conditions of the schedule stipulated for the "best" individual bloom in the show. The cash prize was to be divided equally, but there were no instructions from Judges or Secretary as to whom belonged the "bit of cardboard;" and as there was a dual claim of ownership I considered the certificate was of no intrinsic value, and did not therefore contest the case. Had I done so it may have generated bad feeling, and a probable "scene in court." I may, however, say that Empress of India—a fine bloom—was chosen from my stand, Mrs. Alpheus Hardy being drawn from my opponent's board. By a curious coincidence this happened in the same year as in the case cited by "Forlorn," 1893.—W. S., *Wilts.*

[Our respected correspondent implies that the certificate was withheld from both exhibitors. In that case the Judges were consistent, and admitted their incapacity to decide the point. We can understand its being difficult with the two sections in competition, and though we have never seen a bloom of Mrs. Alpheus Hardy equal to a high-class specimen of Empress of India, it is of course possible that the first-named in the contest in question was superior to any that have come under our notice. We have to confess to believing in the dictum of a celebrated man that "difficulties are things to be overcome," and we know from no small experience that the easiest way of evading them at flower shows is to give equal prizes. In the case of money prizes it may be equitable enough, but when a mark of honour is provided in the form of a cup or medal we think it ought to be won by the exhibitor who leads a close competitor by half a point, or even less. It is just as easy to appraise the value of two individual Chrysanthemum blooms on the point basis as it is to determine the relative values of two stands of twelve or twenty-four blooms by the same process. Perhaps neither "W. S." nor our "Forlorn" correspondent (page 108, last week), who got the money, may be able to say whether the Judges had recourse to that the most exact of all methods or not. It would be interesting to have the information.]

BELFAST CHRYSANTHEMUM SHOW REFLECTIONS.

THE competition for the Victoria Diamond Jubilee medals and £100 in cash, presented by the Lady Mayoress of Belfast and the ladies of Ulster, and distributed over seven prizes in one class, was undoubtedly a feature of attraction at this great show. Another feature observed by many visitors to the show was the manner in which the rules of societies can be ignored.

Firstly.—In the second prize stand in the Jubilee championship

competition for forty-eight blooms, Japanese, in at least thirty-six varieties, not more than two of any one variety, and all of which must be in commerce, we find Mr. W. Mease of Downside, Leatherhead, exhibiting the "primrose sport" of Madame Carnot. Since then it has been put in commerce as "Mrs. W. Mease." There was an objection lodged against the stand on account of this bloom, the variety not being in commerce, but the officiating Judge, Mr. E. Beckett, Aldenham House, Elstree, qualified it by declaring it to be Yellow Madame Carnot, as introduced by Mr. H. J. Jones of Lewisham, and after being adjudicated upon it was re-labelled as such. It was quite evident that Mr. Mease had not complied with the rules of the schedule, and if Mr. Beckett had ever seen Yellow Madame Carnot as introduced by Mr. H. J. Jones he could not have been mistaken, as the variety before him was a very pale primrose in colour. I considered it quite as distinct from Yellow Madame Carnot supplied to me by Mr. H. J. Jones as Yellow Madame Carnot is from the original. It was therefore a stand which some judges would not hesitate to disqualify on account of this bloom.

The second feature of attraction was the manner in which Japanese blooms can be manipulated with cardboards to appear to the best advantage. Regardless of the rules of the National Chrysanthemum Society, which specify that all Japanese blooms shall be shown on cups not exceeding 3 inches in diameter, in the third prize stand exhibited by Mr. Henry Perkins of Greenlands, Henley-on-Thames, we saw a fine illustration of cardboarding blooms. We observed a bloom of Pride of Exmouth with a circular cardboard $5\frac{1}{2}$ inches in diameter, a thin bloom of Mutual Friend with a circular cardboard of 5 inches in diameter, while thirty-one blooms in all on this stand were assisted and propped with cardboards of various shapes and sizes.

The object attained by using these supports was quite as apparent as were the advantages derived therefrom, especially on suitable subjects. A thin bloom can be made to look much larger and fuller when not pulled down too tightly without seriously detracting from the depth. In fact, when carefully and properly done, as it was in this case, it makes a considerable improvement on a stand of blooms, and places a co-exhibitor at a disadvantage who shows his blooms on the *bona-fide* regulation cups. I have not yet met an individual Irish exhibitor of Chrysanthemums who has ever had any experience in using extraneous aid in setting up blooms further than the regulation cup prescribed by the N.C.S.

Some readers may ask, Why did you let this question lie dormant so long? I would rather an older exhibitor had taken the matter up, but as an Irish exhibitor who made his *débüt* in this class, I have dared to throw down the gauntlet. Thanking you in anticipation for insertion, and for the information it may elicit for the benefit of your many "Mum" loving readers.—PETER BROCK, *The Gardens, Glenmor, Drogheda.*

AN INTERNATIONAL CHRYSANTHEMUM AUDIT IN FRANCE.

I HAVE read with interest "Sadoc's" criticisms (page 84) in the *Journal of Horticulture* of 27th January, and, as affording a guide for the cultivation of the autumn queen in England, I agree with him that it is of little value; but as to the audit being "purely a sentimental one," I think he has drawn a wrong inference. I consider that the audit furnishes strong evidence that many of the varieties which succeed in England are, broadly speaking, failures in the other countries named, and the *vice-versa* has often been witnessed in England, notably in the case of American varieties.

Reading from the Journal (page 63) of 20th January, it also appears that the audit comprises "the best fifty Chrysanthemums," and from the prominent position given to some well-known "plant varieties," such, e.g., as W. H. Lincoln, Wm. Tricker, and others, I think it may be reasonably assumed that "large Japanese exhibition blooms" was not solely in the minds of the organiser or of the voters. Possibly "Sadoc" has overlooked this point. However, in an Italian audit I should certainly place Le Colosse Grenoblois in the first half-dozen and Mrs. C. Harman Payne (which loses its coarseness to a considerable extent here) and Philadelphia, perhaps the finest Japanese incurved, in the first twenty-four, which would also include Good Gracious, Vivian Morel, and Australian Gold; but Mons. Chenon de Leché would take a lower position with me. The colour of Madame Ed. Roger has probably something to do with its being fourth in the list, but if it prove to be a good Japanese incurved it will take a high place here.

Of course, in such an extensive and mixed audit it is undesirable to place too much reliance; but from several years' experience in this country I do not find very much fault with it. Audits of Chrysanthemums in England, obtained by even a limited number of voters, rarely give satisfaction or by any means receive universal approval, and I venture to think that all audits of the golden flower are most reliably made from representative exhibitions when statistics are recognised as facts.—H. BRISCOE-IRONSIDE, *Pallanza, Lago Maggiore, Italy.*

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE annual meeting was held in the Society's rooms, The Museum, Orchard Street, on Wednesday evening, the 2nd inst., for the election of the officials for the current year and the passing of the accounts for the year ending December 31st, 1897. Mr. John J. Newsham was elected Chairman. The Secretary then read the statement of accounts, which had been previously passed and certified by the Auditors. The balance in hand on the general account is now £96 11s. 4d., being an addition on the year's working of £11 10s. 3d., which was considered satisfactory, taking into account a much increased payment for prizes at the last annual exhibition in consequence of the increased number of competitors

in the various classes and about £10 paid for decorating one of the public halls, at the request of the Corporation Committee, on the occasion of her Majesty the Queen's visit to Sheffield in May.

The Benevolent Fund for professional gardeners, established by this Society, also shows an increase in the balance in hand, the amount available for the purpose of assisting members in case of sickness being about £60. The balance in hand of the Library Funds, for the purchase of new works upon horticultural subjects, is £5 0s. 6d.

On account of the great uncertainty of the weather when the Society holds its annual show, it was deemed necessary to make some provision for probable loss in the income from that source should unfavourable weather be experienced, such as occurred a few years ago, when the Society's balance in hand fell to 9s. After a little discussion it was unanimously decided to transfer £50 to a reserve fund for the above purpose.

The Lord Mayor (Alderman G. Franklin) and the Master Cutler (Maurice G. Rodgers, Esq.), and other gentlemen of influence were added to the Society's list of Vice-Presidents. The annual dinner is fixed for the 16th inst.

HIGHGATE AND DISTRICT CHRYSANTHEMUM SOCIETY.

THE annual general meeting of this Society was held on the 2nd inst., the President, Mr. H. W. Birks, presiding. The minutes of the last annual general meeting having been read and confirmed, the Treasurer (Mr. J. McKerchar) read the financial statement, which showed receipts for the past year amounting to £165 6s. 6½d., the expenditure being £161 2s. 7½d., of which £87 2s. had been awarded in prizes, leaving a balance in hand of £4 3s. 11d. The Secretary (Mr. W. E. Boyce) read the annual report, which, after relating the success of the last exhibition over any previously held, went on to say that the Committee had decided to hold the exhibition for 1898 at the Holloway Hall, and they had every reason to believe that it would be the best exhibition ever held in the north of London. The President, in moving the adoption of the balance-sheet and report, said he thought they had fulfilled their mission. They had not contributed perhaps to "the gaiety of the nations," but they certainly had contributed to the gaiety of Highgate in providing residents with a two-days exhibition which, coming as it did in the month of November, proved very acceptable. It was acknowledged on all hands, even by the Judges, whom he knew as critical men, that the exhibition was entitled to all the praise bestowed upon it. There was also another test to which many societies could not submit—that of finance, and they had to congratulate themselves that, judged by that test, they came out well. Votes of thanks were passed to the retiring President and officers, also to the Vice-Presidents and special prize donors.

Mr. Birks then introduced Mr. C. F. Cory-Wright as the President for the ensuing year. Mr. Cory-Wright said that he did not wish to begin his presidency by finding fault, but he thought they had made a mistake in letting their late President go. Mr. Birks had made it very difficult for anyone to follow him, but at the same time he would endeavour to promote the interests of the Society as far as possible, and hoped at the end of the year they would be in no worse position. The election of officers then took place, Mr. McKerchar and Mr. W. E. Boyce being re-elected Treasurer and Secretary respectively. Mr. Boyce stated that the schedule was well in hand, and, in fact, ready for the Committee to finally settle. The schedule would be larger than the last, and there was every prospect of a very successful year, the new President giving special prizes to the amount of nearly £12, Mrs. C. F. Cory-Wright £2 2s., and, in addition, he (the Secretary) had obtained new special prizes to the amount of £15.

WASTEFUL USE OF ARTIFICIAL MANURES.

NEED I say I was surprised and astonished to read the remarks on artificial manures by Mr. "A. D." on page 81? It is past my comprehension how a well-known critic like your correspondent could have fallen in such errors over such a trifling subject. I think I see him holding up his hands in horror at the wasteful way in which I used those manures; but let us have fact to fact, and then see how he stands.

Mr. "A. D." tells us that the 2 lbs. of basic slag and 12 ozs. of kainit per square yard is "82 lbs. per rod and just about 6 tons per acre," and goes on to assume that as my "plants and fruit" . . . were not "one whit better than Tomato growers ordinarily obtain on ordinary soil, the manures mentioned were either practically worthless or not utilised by the crop," and positively adds that the above quantity ought to be enough for a dozen dressings at least.

I think I stated very clearly that the 2 lbs. of basic slag and 12 ozs. of kainit were applied, not for the purpose of feeding plants—for that was a consideration of secondary importance—but to kill root eelworm, which I knew was present in my soil. I have every reason to believe that the above dose has killed the eelworm, consequently it has accomplished the work for which it was applied; but Mr. "A. D." says the above quantity was sufficient for a dozen dressings. He evidently knows by this that if I had used 1 oz. of kainit and 2½ ozs. of basic slag per square yard it would have killed the eelworm quite as well as the quantity I used. Mr. Iggulden tells us on page 76 that "he forks into his Tomato borders 4 ozs. of kainit, 8 ozs. of basic slag, and 8 ozs. of soot;" but evidently this quantity is not enough to destroy the eelworm, or why does he use the phenyle afterwards? Can Mr. "A. D." make his assertion agree with actual facts? I think not; and I might add that he, like the rest of us, has still a great deal to learn about the use of artificial manures. Mr. "A. D." knows as well as I do that the manures I used are retained by the soil—i.e., they cannot be washed away. This being the case, the

eelworm are dead and there is sufficient manure left for another crop of Tomatoes and ten crops of Grapes; so your correspondent must admit that there is no waste, but that there was a method in my madness.

Many Tomato growers actually lose 75 per cent. of their crop owing to bad attacks of eelworm. I do not claim to have obtained more fruit than growers "ordinarily obtain on ordinary soil," but that I had a full instead of a quarter crop is a satisfaction to myself, and makes me again ask, Where was the waste? As for the manures I used poisoning the borders, that is like begging the question, for I can safely say that the quantity I used would not do so; and to show how absurd it is to suppose they would, I would ask, How was it possible for me to grow a good crop of Tomatoes in the borders if they were poisoned?

I have seen "fine crops of Tomatoes obtained from very ordinary soil, assisted by soot and light sprinklings of artificial manures;" I have seen heavier crops grown in better soil when the sprinklings have been given every day; and what is more, I have grown Tomatoes in ten parts of pure clay, eighty-eight parts of silver sand, and two parts of powdered chalk fed with artificial manures quite as successfully as others in three parts of turfy loam and one part of decayed manure. I presume Mr. "A. D." has carried out a few experiments with artificial manures. Can you ask him to let them be published in "our Journal," and perhaps they will obtain for him the thanks of others besides—W. DYKE.

THE NOTTINGHAMSHIRE HORTICULTURAL AND BOTANICAL SOCIETY.

ON the 27th ult. the officers, members, and friends of the above Society partook of their annual dinner together at the Spread Eagle Hotel, Goldsmith Street, Nottingham, their host being Mr. Councillor Charles Smith, the Chairman of the Committee of the Society. The report read by the Secretary (Mr. J. M. Stewart) was pleasant hearing, because it gave a cheery account of a state of things which does the officers much credit. The Society does its work in a very quiet and unostentatious manner, and deserves more support than it gets from the county gentry. The town does its fair share in supporting the Society from the members of Parliament, the Mayor and Sheriff, and many of the members of the municipality, through all grades, including a good proportion of the large number of working men gardeners who are so numerous in Nottingham.

Among other features are periodical visits made to notable places, partly for holiday amusement, but more particularly for the educational advantages which visits to great gardens give to those who have observant eyes and open minds. Rufford Abbey and grounds, by kind permission of the Right Hon. Lord Saville, were visited on July 1st. Mr. J. Doe, the head gardener, did all in his power to make the visit interesting, and the Abbey with its rich store of art treasures was thoroughly enjoyed, as well as were the well managed gardens and grounds. Sandringham Gardens, by kind permission of H.R.H. the Prince of Wales, were visited on Wednesday, July 28th. Through the kindness of Mr. McKeller the plant and fruit houses were thrown open for inspection, and every possible arrangement was made for the visitors to make a thorough inspection of the beautiful gardens and grounds.

The Society does not lay itself out for large shows, experience having taught the officers that Nottingham people having such splendid displays of both flowers, fruits, and vegetables every week in the market, such as few towns possess, do not care for much more. One summer show is, however, provided; that of last year was held in the grounds of the Arboretum on July 14th and 15th, and was, without doubt, the finest the Society has held for a number of years. Through the kindness of the Corporation of Nottingham the Arboretum will be available again this year, and it is hoped and believed in future years.

Other shows are made more educational. For instance, a fruit meeting was held October 28th in the Mechanics' Lecture Hall, when over 300 dishes were staged. At the same meeting a paper was read by Mr. Hy. Merryweather, jun., on "Hardy Fruit Culture." This paper was a most able one. A Chrysanthemum meeting was held on Wednesday, November 17th, in the Mechanics' Lecture Hall. The numerous and representative exhibits sent in by the members raised the meeting to the rank of an exhibition. Able and practical papers were read by Mr. R. J. Walters, on "Growing for Exhibition;" Mr. E. Palmer, on "Growing for Decoration;" Mr. N. German, on "Growing for Market;" and Mr. S. Thacker, on "The Staging of the Chrysanthemum." These papers proved of great value to all interested in the cultivation of the Chrysanthemum.

The Society's gold medal has been awarded to Mr. J. H. Goodacre, The Gardens, Elvaston Castle, for a superb group of Malmaison Carnations exhibited at the Arboretum Show. Certificates of merit have been awarded to Messrs. Armitage Bros., Limited, for a collection of Peas exhibited at the Arboretum Show; Mrs. Theresa Rothera, for a table decoration of outdoor grown fruit, flowers, and wild Grasses; Mr. C. J. Mee, for six bunches Gros Colman Grapes exhibited at the fruit meeting; Mr. E. Wadsworth, for a collection of Leeks and Carrots; Mr. E. Palmer, for a collection of double Primula plants; and Mr. E. H. Eccleston, for twelve Chrysanthemum blooms of Japanese Chrysanthemums.

The Treasurer of the Society was able to announce that a very substantial balance on the right side of the ledger would appear in the annual balance-sheet. Since the report was printed another meeting has been held, when Mr. H. Weeks of The Gardens, Thrumpton Hall, the raiser of so many good Chrysanthemums, read a most excellent and practical paper on the subject he knows so well, "The Chrysanthemum."

WEATHER IN LONDON.—During the past week we have had almost the first touch of winter, as characterised by a light fall of snow on the morning of Friday last. Neither in the metropolis nor in the surrounding country did the snow remain on the ground. On one or two mornings we have had moderately sharp frosts, notably on Tuesday. Saturday was dry, and a cold wind prevailed, but Sunday was very showery, with occasional gleams of brilliant sunshine. Monday was cold, as was Tuesday throughout the day, rain falling in the afternoon. At the time of going to press on Wednesday it was cold and foggy.

WEATHER IN THE NORTH.—February entered with wet and tempestuous weather. Throughout the night of the 1st a gale raged from the S.W., accompanied by very heavy showers. The weather cleared on the afternoon of the 3rd, and took a decidedly wintry turn. Since then frosts of from 3° to 5° have occurred, and the higher hills are densely covered with snow, while the lower grounds were on Sunday also thickly coated. Monday was a clear wintry-looking day, and Tuesday opened clear and keen with no sign of change.—B. D., *S. Perthshire*.

GARRYA ELLIPTICA.—As a flowering plant the male form only of this Californian shrub deserves a place in gardens, the flowers of the female form being small and inconspicuous. As an evergreen shrub both forms have considerable merit. The flowers of the male plant are greenish yellow, and produced in pendulous catkins several inches in length from the upper nodes and apices of the previous year's growth. The time the flowers are produced depends on the mildness or severity of the winter. In mild weather the flowers commence opening about the middle of January; at other times they are a month later. About London it does well when planted in the open, further north it requires the protection of a wall. When grown against a wall the main branches only should be supported, the others being allowed their freedom. Two large plants in the gardens at Wimbledon House are growing against a wall in this manner, and flower with exceptional freedom.—W. D.

ISLE OF WIGHT.—The Isle of Wight Horticultural Improvement Association held its monthly meeting at Newport on Saturday last. Mr. J. H. Parkin presided. Mr. J. Hygate, gardener, The Briary, Cowes, gave a thoroughly practical address on "The Cultivation of Grapes in a Cool House." The Black Hamburg was the variety he strongly recommended for the purpose. During the subsequent discussion the question of Grape growing in the open air for wine making was discussed, as there are positions on the Undercliffe believed to be suitable for the purpose. The exhibits staged were of first-class quality, and well merited in each case the Association certificate for cultural merit which they received. Mr. H. Drover, florist, Ventnor, staged a collection of Cyclamen and Primulas; Mr. A. J. Cole, Broadlands, Sandown, showed a specimen Cyclamen from seed sown in August, 1896, which had eighty blooms upon it, and the plant itself was over 2 feet through; Mr. G. Honeybourne, gardener to Lady Daly, Ryde, staged a fine healthy plant of Dendrobium Hilli with six spikes. At the close of the meeting fourteen new members were elected. The first Saturday in March Mr. J. H. Parkin will give a paper on "Asparagus."

EARLY HARDY FLOWERS.—The following plants were flowering in the open ground at Hodsock Priory, Notts, on the 1st of February, showing the mildness of the season:—Single and double Snowdrops, St. Brigid Anemone, Tritelia uniflora, Winter Aconites, Pansies, Primroses, all colours, white, yellow, red, rose, and blue; Violets, single and double, in variety; Honesty, double Daisies, Christmas Roses, Lenten Roses, in all shades of colour, grand objects; Strawberry Black Prince, Arabis alba, English Yew, Crocus Imperati, Leucoium vernum, very fine; Iris reticulata, Hepatica, common blue; Hepatica angulosa, Iris reticulata Krelagei, Iris stylosa, Jasminum nudiflorum, Polyanthus Gold Laced, Dutch Crocus, Muscari azureum, Scilla bifolia, Cardamine rotundifolia, Scilla sibirica, Helleborus foetidus, Cyclamen Coum, the brightest jewel in Flora's winter crown; Anemone blanda, Orobis alpestris, Lonicera fragrantissima, common Periwinkles, Erica carnea, Berberis aquifolium, Kerria japonica, Wallflowers, Pyrus japonica, Polygala chamaebuxus, in full flower, said to bloom in May; and Brompton Stock. This is my thirtieth winter here, and I have never seen so much bloom so early in the year before.—J. MALLENDER.

FLUED GARDEN WALLS.—In answer to Mr. Geo. Dyke, on page 56 of the *Journal of Horticulture*, respecting flued garden walls, I may inform him there is now existing at The Gardens, Trafalgar, Salisbury, Wilts, the old flues in the walls, with about six chambers, but the chimney is not to be seen. The flues run about 100 feet long.—G. FULFORD.

ARTICHOKES AU GRATIN.—Well, wash and peel 3 lbs. of Artichokes, trim them into the shape of small Pears, then throw them into boiling water with a pinch of sugar and some salt. Let them boil about twenty minutes, then drain off the water. Add 4 ozs. of butter, one small Onion chopped very fine, some pepper, a gill of milk, and 4 ozs. of grated Parmesan cheese. Stir gently with a wooden spoon, then turn into a baking dish. Sprinkle the top with bread crumbs; place in a very hot oven to gratinate.—A LADY.

HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—A meeting of the above Society was held on Tuesday, February 1st. Mr. Geo. Picker, Hesslewood Gardens, occupied the chair, and there was a very large attendance. The essayist for the evening was Mr. J. P. Leadbetter, Tranby Croft Gardens, and the subject "The Cultivation of the Malmaison Carnation." The essayist described all the requirements of this now very popular flower. A good discussion followed the essay, and the manner in which Mr. Leadbetter answered his critics tended to show how well he was acquainted with his subject. Mr. J. Barker, gardener to W. P. Birkenshaw, Esq., showed several plants of Cypripediums in variety. A hearty vote of thanks to the essayist and Chairman terminated one of the best meetings the Society has had.—G. W. G.

CHEIRANTHUS MUTABILIS.—The plant under notice is one which might with advantage be made use of as a winter-flowering plant for the cool greenhouse. It grows readily in light loamy soil, and makes a compact little bush, with long narrow leaves. The flowers are lilac, or sometimes almost purple, a quarter of an inch across, and produced in long slender racemes. They are at their best from the latter end of November to the end of February, though on a large plant flowers are to be found at almost any time. Cuttings inserted in sandy soil in the spring root readily, and by autumn make good-sized plants. As it is a native of Madeira the protection afforded by a cold frame is necessary during severe weather; at other times it can be grown well outside. A number of plants in flower may now be seen in the winter garden at Kew.—D. K.

DEATH OF MR. G. T. CLARK.—We regret to learn of the death of this gentleman, which occurred at his residence, Talygarn, Glamorganshire, on the 31st ult., in his eighty-eighth year. Mr. Clark was a remarkable man, combining extraordinary business capacity with considerable literary ability, and was endowed with great power for historical research. After an active early life he became trustee under the will of the late Sir John Guest of the now celebrated Dowlais Iron Works, which seem to have been at that time in such an unsatisfactory state that he was advised to wind up the estate; but as this would have involved the dismissal of nearly 12,000 men and the ruin of their homes he determined with the co-operation, as trustee, of the late Lord Aberdare, to save the great works and make them prosperous. He succeeded beyond the most sanguine expectations, became known as the "Saviour of Dowlais," and a benefactor to South Wales. Eventually, as may be remembered, Lord Aberdare became President of the Royal Horticultural Society, on the overthrow of the South Kensingtonian dynasty, and called Mr. Clark to his aid on the Council, during probably the most difficult period of the Society's existence, and then was laid the foundation of its present prosperity. Mr. Clark took considerable interest in gardening, but more particularly in forestry, and planted with prodigality. He lived to see a dense forest of choice Conifers established around his home, and draw each other up to a great altitude in the arboreal jungle, for he would have none destroyed. Mr. Clark was a giant in stature and intellect. With a great and generous heart he was ever ready to help those who were in need, and in all projects that were established for the public good in the district, in which he will be long and gratefully remembered. It may be added that on the afternoon of his death Mr. Clark had so far recovered from an attack of influenza that he was able to revise some proofs of a book which he was preparing on the pedigrees of Glamorganshire families. This work he carried on in his study, which he also made during his illness his bedroom as well. Shortly before four o'clock he spoke to the nurse, and said he would like to lie down. She assisted him on to the bed, and it would appear that he died almost immediately from syncope, accelerated by the attack of influenza.

— **SUSSEX RAINFALL.**—The total rainfall at Stonehurst, Ardingly, for the past month was 0.74 inch, being 1.39 inch below the average. The heaviest fall was 0.28 inch on the 5th. Rain fell on nine days. The maximum temperature was 53° on the 22nd, the minimum 30° on the 11th. Mean maximum, 45.25°; mean minimum, 39.02°; mean temperature, 42.13°, which is 5.64° above the average of ten years. Vegetation forward enough for the middle of March, and cooler weather would be welcomed to keep fruit trees back.—R. I.

— **JANUARY WEATHER AT HODSOCK PRIORY, WORKSOP, NOTTS.**—Mean temperature, 42.9°. Maximum in screen, 57.1° on 30th; minimum in screen, 28.9° on 10th. Minimum on grass, 19.1° on 10th. Sunshine twenty hours, or 8 per cent. of possible duration. Rainfall, 0.45 inch. Rain fell on ten days. Warmer than any January of the last twenty-two years except 1884, when the temperature was 43.0°. Drier than any except 1880, when only 0.22 inch fell, and duller than any of the last seventeen years except 1885, when the sunshine was only fourteen hours.—J. MALLENDER.

— **JANUARY WEATHER IN GLAMORGANSHIRE.**—Mr. W. Mabbott writes from Gwernllwyn Gardens, Dowlais:—"The following is a summary of the weather here for the past month. Rainfall 2.07 inches, which fell on fourteen days; maximum 0.48 on the 5th. Average maximum temperature 43°; highest reading 48° on the 3rd. Average minimum 34°; lowest reading 25° on the 9th. There were seven occasions when the minimum was above 40°; below freezing point on nine days. There were twenty-five sunless days. The wind was in the W. and S.W. on fifteen days, and in the E. and S.E. on eleven days; very quiet on the whole and the weather open. A very small rainfall for this district. Fogs were very dense on a few occasions."

— **LONICERA FRAGRANTISSIMA.**—For the last two months a large plant of this Chinese Honeysuckle has been flowering freely at Kew, and now (February 3rd) every shoot is covered with pretty sweetly scented white flowers. The flowers are usually produced in pairs, several springing from every bud on last year's growth. Growing close by are several plants of *L. Standishi*, a species with which the former is often confused. A glance at the two together shows that they are quite distinct. In the former the leaves are shorter, more ovate, not so acuminate, and not nearly so hairy as in the latter; and while many of the leaves of the first named are retained during the whole winter, those of *L. Standishi* usually fall before the flowers commence to open. Flowering, in midwinter, it will be found worthy of a place in any collection.—KEWITE.

— **THE WEATHER LAST MONTH.**—January was extremely mild, similar to January 1882 and 1890, but milder than either. The wind was in a southerly direction on twenty-four days. Total rainfall was 0.78 inch, which fell on nine days, and 1 inch below the average for the month. The greatest daily fall was 0.32 inch on the 4th. Barometer (corrected and reduced), highest reading, 30.629 inches on the 15th at 9 P.M.; lowest, 29.385 inches on the 1st at 9 A.M. Thermometer: highest in the shade 56° on the 30th; lowest, 27° on the 23rd. Mean of daily maxima, 47.09°; mean of daily minima, 36.80°. Mean temperature of the month, 41.94°. Lowest on grass, 21° on the 10th and 23rd; highest in the sun, 82° on the 12th. Mean temperature of the earth at 3 feet, 42.38°. Total sunshine, 41 hours 40 minutes. There were fifteen sunless days.—W. H. DIVERS, *The Gardens, Belvoir Castle, Grantham.*

— **THE R.H.S. EXAMINATION.**—May I be allowed to supplement the advice given by yourself (page 93) and "A. D." (page 102), urging young gardeners to attend the above examination? We are occasionally met with the despairing cry that "the time for preparation is so short." In reply to this I crave permission to ask young gardeners to take a common sense view of the matter, and to bear in mind that the practical work which they have been engaged in since the age of sixteen is the very best preparation they can have. A glance at past questions reveals the fact that the majority of them bear either upon everyday work, or upon scientific matters which careful readers may have observed in the *Journal of Horticulture* from time to time. Good, honest, practical work, coupled with intelligent study of the gardening papers and an occasional contribution to the "Young Gardeners' Domain," ought to suffice to pass any of your readers. Candidates need not trouble themselves about some of the questions, and if they wait for a scheme of examination which everybody regards as being perfect, nothing will be done. The great universal *now* is the only time any of us can call our own, so let us make the best use we can of it, and by submitting to tests let us find out our weak points, remembering that the best man in the long run is the one who learns most from his failures.—PRACTICE WITH SCIENCE.

— **A FROSTLESS JANUARY.**—It is not often that we get a frostless January; but the precedent of those years in recent times that have opened with so mild a month as we have experienced this year warns us against thinking that winter is over. In 1873 there was no touch of winter till January was over. Then, on February 1st, an intense frost set in and lasted into March. The following year was better; it opened in a similar way, and kept on without a break, so that harvest was in July. In 1878, again, there was a frostless first month, and vegetation came on early, only to be nipped by frosts and chilly weather in March and April, an experience that was repeated in 1892. So that the balance of experience is against an open January being followed by an unbroken period of fine spring weather.

— **THE NATIONAL DAHLIA SOCIETY.**—In common with other members of this estimable Society, I am in receipt of the present year's report and schedule of prizes at the great autumn show at the Crystal Palace, on the 2nd and 3rd September next. This is undoubtedly the great Dahlia exhibition of the season, and it has as such no rival. All the same, every autumn exhibition all over the kingdom not only finds Dahlias in the various sections prominent, but they are liberally encouraged by prizes. Dahlias have grown into popular favour in a remarkable way—indeed, they now rank with the Rose and the Chrysanthemum, in their respective seasons, as people's flowers. The National Society has done very much in creating this popularity, for its exhibitions are of the finest, and novelties find at them every encouragement. But in looking over the schedule of the National Dahlia Show, I am struck with the great diversity found in the amounts offered as prizes for these beautiful flowers as compared with what are offered generally for Chrysanthemums. With Dahlias, £4 10s. is thought to be a good first prize for sixty show blooms. Were this a class for sixty Chrysanthemums, fully three times the amount would be looked for. In the case of the large class of eighteen varieties of Cactus Dahlias, a total of 108 flowers, the first prize is only 40s., although amateurs come off better, as they get a first prize of 60s. for 72 blooms. Taking the schedule all through, one sees prizes of the most reasonable kind, and yet great competition results. There is nothing to stimulate greed in them, and that is a pleasing feature. The rage which seems so strongly to exist in the Chrysanthemum world for big money prizes will some day bring about its own cure, in the utter impossibility of committees to find them. Why cannot we see Chrysanthemums exhibited a little for love as Dahlias are, and less to secure big cash amounts?—A. D.

THE REVOLUTION IN INSECTICIDES.

ALL those who have had to do with greenhouses, especially small amateurs, know what a terrible nuisance the insect pests are, and how very nasty and unpleasant have been the means used to get rid of them, and how oftentimes, after all the trouble that has been taken and the unpleasantness endured, the aphides especially have laughed at these attempts. There have been dangers, too, connected with the fumigation, for should the tobacco paper or cloth used flare up into a blaze injury has often been done to the plants, while the person employed in the operation must come out from the house into which he has introduced the fumigator pale and miserable. I remember seeing in a large and well ordered establishment an ingenious contrivance by which the man who conducted the fumigation got admission into the house by a hole low down, so that he was beneath the influence of the smoke.

But this is all now changed. The introduction of vaporisers does away with all the inconvenience and effectually carries out its object. There are two of which I have heard, Richards' and Macdougall's; of these I have only tried the latter. It is simple and economical, while it completely destroyed all semblance of aphids in my greenhouse. It left a smell of nicotine for a short time, but this soon passed away. The house was operated upon about three weeks ago, and I have seen no trace of aphids since. A friend says that he has tried Richards'; it not only destroyed the aphids, but also those terrible pests scale and mealy bug. This is a boon which those who have had to do with *Stephanotis* and other plants of similar character will greatly value, and altogether this new invention will be received with great thankfulness.

There is, however, another side of this picture, as there is in most things. I remember, for instance, many years ago that a flourishing factory was established in the West of Ireland for the purpose of extracting iodine from seaweed, and everything for some years went on well, as the drug fetched a high price, and was not easy to procure; but suddenly it was discovered in Germany in its natural state, and consequently the whole affair in the West of Ireland came to grief. Have we not heard, too, how the profitable culture of the cochineal insect in the Canaries was completely ruined by the discovery of aniline dyes? and so now it has been with the manufacturers of tobacco paper and tobacco cloth. One well-known manufacturer of the former told me that the discovery of these vaporisers entailed on him a loss of £300 a year, while a manufacturer of tobacco cloth told a friend of mine it was not the slightest use making any more. But this is always the case when any new discovery is made; still, with this drawback, I think that all gardeners will gladly welcome the vaporisers.—D., *Deal.*

REMARKS ON PEACH TREES.

FOR a long time I have observed that Peach trees have their length of days and well-doing much affected by the way in which they have been budded and trained in nurseries. Trees ordered and obtained from nurseries are usually dwarfs, half-standard, and standards or riders, and have stems of about 1 foot, 2½ feet to 3 feet, and 5 to 6 feet respectively.

The method generally adopted in budding to produce such trees is to bud the stocks at the various heights named, and from that point of union commence the training of them. Some considerable shortening of the first growths takes place near to this point, with the view of laying the foundation of the head. More of this knife work than is necessary is resorted to, and it too often lays the foundation for corruption and decay. A great enlargement takes place at the point of union, which enlargement becomes unhealthy, and transmits its unhealthiness to the branches.

In a long experience I have seen it to be, I think I may say, invariably the case, that when the head of the tree starts—not from the union of the bud with the stock, but from the top of an extension of the bud and right away from the union—the life and general health of the tree has been more prolonged, and altogether more satisfactory. In other words, when a half and a full standard have their heads started 2 or 3 feet above the union of the bud with the stock they are less subject to gangrene and decay, whether grown under glass or outdoors.

In reference to open-air trees that have no protection at any time from glass, it has recently been asserted that there is no reason why good healthy and productive Peaches should not, with good management, be grown in every part of Great Britain. I should say there are few gardeners who have had the experience necessary to prove this assertion to be correct. It has been our lot to attempt the culture of Peaches on open walls, where most seasons they remained semi-ever-green all winter. Under such circumstances it would be interesting to know how success could be secured. No cultural attempt could be more futile, and it is best described by a waste of time and means.

Having referred to the ripening of wood, I once had a most striking example of the fact that upon the proper ripening of the wood depends, more than on anything else, the success of outdoor Peach growing. In carrying out some re-arrangements at Archerfield in 1858 I moved from under glass to the Peach wall a tree of *Violette Hâtive* Peach that I judged to be quite twenty years old. It was perfectly ripened, and it was the only tree on the wall that bore a crop of fruit in 1859.—D. THOMSON.

HARMFUL AND HARMLESS GARDEN MOTHS—15.

To a small, but very distinct family of moths, some members of which are noticeable in gardens, has been given the formidable name of the “daggers,” suggested, however, only by the form of certain markings visible on the wings of most species. But it so happens, as we discover by individual names, what some people think dagger-like, appears to other eyes to be of a different shape. In the state of caterpillar all these are distinguished by the fact that they are hairy, whereas the bulk of Noctuas come from smooth caterpillars. We cannot have a better specimen of the group than the species called from its commonness the dagger (*Acronycta Psi*), or its relative the dark dagger (*A. tridens*), though really as to darkness of colour the difference is slight; the two species closely resemble each other.

Both species bear upon the wings figures which have been compared to the Greek letter *psi*, or to a trident, black, upon dark grey or brown, also there are additional black markings. The first of these is seen everywhere in June and July, even about London and other large towns, resting by day on trees or walls; the second is more local, but distributed over our islands. During August, September, or even as late as October, the conspicuous caterpillar of the common dagger is feeding upon Hawthorn, Elm, and Lime; it also occurs upon fruit trees, especially Pear and Plum. It is yellow and black, with a shining head, and a coating of grey hairs. In the middle of the back is a slender upright horn, and a broad hump upon the last segment but one. The cocoon is spun up in a crevice, and the chrysalis remains there through the winter. We find the caterpillar of *A. tridens* about the same time on various trees and shrubs. In appearance it differs from the commoner kind considerably, being chiefly black, ornamented with orange and white spots. It has not the horn on the back, but one at the last segment, pointing backwards; it is also slightly humped; the head is very hairy.

Quite a cockney insect is the Sycamore dagger (*A. Aceris*), frequent about London and in the south and east of England. The moth flies in June; the caterpillar occasionally salutes us by falling upon us from a tree when a strong wind prevails in August or September, or we see a full-fed one in the act of crawling down to make its cocoon near the surface of the soil. Named after the Sycamore, it is more often, I think, a dweller upon the Horse Chestnut, and rarely upon the Oak.

Certainly a handsome caterpillar; the greyish body exhibits a series of snow-white spots edged with deep black; the ornamentation is completed by pencillings of orange-yellow silky hairs. There is nothing showy about the moth; it is some shade of grey, having lines and streaks of a smoky tint; the dagger-like markings are indistinct. The Poplar dagger possesses the Latin name of *A. megacephala*, in allusion to the somewhat large head of the caterpillar, which I have frequently taken off Poplars in the west of London; it seems to occur generally throughout England. This caterpillar, when not feeding, reposes on a leaf in a bent posture, the head being drawn round to touch the tenth segment. Upon the white head are two black blotches and a triangular mark; the body is very dark brown relieved by red and white spots placed in pairs. It is full grown in August; the moth appears in June, and closely resembles the preceding, only its colours are rather lighter.

The coronet moth is now and then noticeable upon a garden wall in July, the brown wings having a decided tinge of green, also two white spots, and some dark mottling. Why it should be called by this name is not obvious; certainly the thorax is crowned with a crest of brown and white, but it is not more remarkable than those which many other Noctuas show. Though the Latin name of *Acronycta Ligustri* associates the species with Privet, it is more common to find its caterpillar upon the Ash. It has a head of delicate green, almost transparent; the body is of a sea-green colour, glossy, having narrow white stripes and a few soft bristles on each segment. Another species of the tribe which is common about gardens, and, in some seasons, does a little mischief to cultivated plants, is designated the Knot-grass moth, or *A. Rumicis*.

If the caterpillar confined its diet to the plant first named, or to one or other of the Docks, we should possibly consider it a gardeners' friend, but, liking variety, it feeds upon a number of low-growing plants, keeping out of view if it can. Should one be dislodged, it rolls down curled in a ring, but soon unfolds, and gallops rapidly over the soil, seeking a new shelter. We have most reason to object to its presence in Strawberry beds, where it has been found feeding about the end of June or early in July. Newman states that it is particularly fond of the alpine varieties, eating the leaves freely; it cannot be removed except by hand-picking. This is another handsome caterpillar of the family we are now describing, yet it does not resemble its brethren; however, in spite of its beauty, we may have to kill it, or pass on specimens to some entomologist, who can diet them on Knot-grass. The head is small, black, varied with brown, and upon the body are arranged a series of markings, which remind us of a tessellated pavement; the colours are black, white, rich brown, and orange red. Also there are on the sides rows of warts, from each of which is a pencil of hairs. The cocoon is spun on the ground, and the moth appears the following May or June.

To mention one more dagger moth, the scarce and local species, *A. auricoma*, is only taken in Kent and Sussex. There are two broods yearly—the dingy moth, which has some faint dagger-like markings, flies in May, and again in August; the caterpillar is taken upon the Bramble during spring and summer. We pass now to a larger species of a different habit, which visits the flowers of June, or sips the syrup spread upon trees for the benefit of thirsty moths. It is called the frosted orange or *Gortyna flavago*. The ample fore wings are more showy than those of any of the dagger moths; the ground colour divides exactly into two parts, bright yellow near the base, and purplish-brown beyond; upon this are numerous spots and lines. The crested thorax has a purple disc and yellow sides. The front pair of legs have long woolly scales attached to them; this possibly suggested the adjective “frosted,” applied to the insect. One reason why the moth may occur about gardens is, that the caterpillar has been taken burrowing in the stems of Potato; also, it feeds on those of Foxgloves and Mulleins, but its preference seems to be some species of *Carduus*. About midsummer it will be found nearly full grown, while the plant where it is ensconced is dying down from the destruction of its pith. This caterpillar is of a dull yellow colour, smooth and flattened; behind the head is a horny plate, and at the tail there is another; by these it is assisted in its mining operations. Though hidden within stems, it frequently falls a victim to the attacks of an ichneumon fly.

The mimicry of Nature is exhibited in the moth oddly called the flame, or *Axylia putris*, which sits in June on some flat surface, with the wings folded round the body, and so just resembles a little bit of stick. This deception is assisted by the colours of grey and brown. Its caterpillar is also brown, having scattered spots of yellow and white; it is said to feed on various low plants during August. A more conspicuous moth, sometimes light in tint, sometimes darker, is the cloud-bordered brindle, or *Xylophasia rurea*, which does not, however, restrict itself to country haunts, but appears in gardens throughout our island, where the caterpillar selects for its food some species of *Primula*, though at a push it can live upon grasses. It is rather stout, reddish, striped with white and brown; during the autumn it eats a little, then hibernates to become full grown in May.—ENTOMOLOGIST.

CATTLEYA TRIANÆ SANDERÆ.

THE many varieties of *Cattleya Trianæ* make this section one of the handsomest and most interesting of the *Cattleya* family. Every year sees new forms of excellent quality introduced, the majority of them first gaining publicity at the Drill Hall shows of the Royal Horticultural Society. If one be sent there it is practically certain to be appraised at its proper value by the members of the Orchid Committee, and will, if worthy, receive recognition, either in the form of a first-class certificate or an award of merit. At the meeting held on January 11th *Cattleya Trianæ Sanderæ* (fig. 19), from the celebrated St. Albans firm, was adjudged the last named award. The flower is of splendid form, great substance, and of rich colour. The sepals and petals are very delicate blush, the latter being broad and slightly fimbriated. The shapely lip is rich crimson, with a suffusion of purple, and a yellow throat.

PROPAGATING ORCHIDS.

THE propagation of Orchids is an interesting and in some cases profitable branch of their culture too little practised by cultivators. Many, when large specimen plants come into their possession, think only of increasing their bulk, when a few young pieces taken off and started on their own account would come away with a vigour and freedom quite beyond what they do on the old plants. Recognising this fact, nurserymen as a rule make a practice of breaking up any old plants that come into their hands with distinct advantage to themselves and the plants operated upon. Not only in this direction is propagation desirable, but amateur growers have often plants that they would like to increase, rare forms and varieties of exceptional value when compared with the typical species.

I am not decrying large specimens, far from it, for no one admires them more, or has oftener deplored in the gardening press the loss of the fine old plants of various kinds that at one time graced our exhibitions. I know of a grower in the West of England at the present time who has, perhaps, some of the finest specimens extant of *Saccolabiums*, *Aërides*, and *Vandas*, and is wont to point to them with pride whenever I have an opportunity of visiting him. Still the fact remains that propagation from offsets or division of the

plant is often desirable, and a few lines on the best mode of procedure may not be out of place.

First, as regards raising seedlings. Such a fascinating and interesting pursuit is this, that many more growers than formerly have taken it up. Now, it is not every amateur grower who has the choice of good parents for their seedlings, consequently they use what are to hand, and duplicate crosses that have been raised years ago by interested cultivators. If I may offer a word of advice to these, let me say, By all means keep your seedling plants, and grow them as well as possible, but do not give them fresh names. If you raise a really good and distinct form, send it to the committee of experts at Westminster, and if they consider it worthy they will give it their "hall mark;" if they do not, be careful to grow it for your own pleasure, but do not add to the confusion already existing by giving it a title it does not deserve.

And while on the subject of seedling raising it is well to point out that there are many fine species now under cultivation that would pay far better for raising than hybrids. Not long ago I saw a beautiful batch of a very rare species making good progress with one of our most successful hybridists, and I have no doubt that these will pay a good profit upon all the trouble and expense taken with them, for it is a kind worth a guinea a leaf even now, though it has long been under cultivation. As an instance of what is still worth raising take the beautiful *Cypripedium Fair-rieanum*, even now comparatively rare, though introduced in 1857.

Many of the *Dendrobiums* again, including some of the more rare forms of *D. nobile*, are far from common. Take *D. n. Ballianum*, *D. n. nobilium*, *D. n. Sanderianum*, and

FIG. 19.—CATTLEYA TRIANÆ SANDERÆ.

others that might be named. It will be long before these charming varieties are obtainable at a low price, and they will pay for propagating from an economic point of view, to say nothing of the wisdom of perpetuating such sterling kinds. In this case, of course, the quickest and best method of propagating is by laying in the stems on moss, cocoa-nut fibre, or similar material, and taking a strong, vigorous young plant from every eye. I have described this way of propagating before in the *Journal of Horticulture*, so I will only say, Choose plump stems that have flowered or else were not sufficiently ripened to flower. Keep them always moist, and separate them as soon as the young shoots begin to root on their own account, eventually potting them singly, and growing them as rapidly as possible.

Calanthes, again, are among the most easily propagated of Orchids, flowering bulbs often producing three or four young ones; or if a quicker mode is desired the pseudo-bulbs may be split into four vertically, and each one of the divided portions will produce a young

bulb if carefully nursed until root action commences. The stems of *Thunia Bensoniae*, *T. alba*, *T. Marshalliana*, or any of the finer varieties of these specimens may be cut into lengths and grown into flowering plants in about a couple of seasons. Division of the old specimens is successful in many instances, some of the more easily grown *Odontoglossums*, *Lycastes*, *Brassias*, *Oneidiums*, *Burlingtonias*, *Masdevallias*, *Cypripediums*, *Maxillarias*, *Coelias*, and *Zygopetalums* being easily propagated in this way.

Such beautiful *Cattleyas* as *C. Hardyana*, *C. Mossiae Wagneri*, *C. Mendelli alba*, *C. Trianae alba*, or any other of the finer albino forms may be freely propagated by division, provided due care is exercised both with the divided portion or pieces lopped off and the parent specimen from which they are taken. To kill the old plant that a young piece has been taken from is worse than useless, so it must be kept in mind that both these and the divided pieces must be nursed a little after division. None but healthy, well-rooted plants should be selected for propagating from, as a weak or semi-established plant may be killed outright by the check caused by taking a piece off it. The young plant is by Nature provided with sound eyes that break easily; the older one has to force a growth out of old and perhaps partially decayed ones, hence the need of great care with the latter. —H. R. R.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—FEBRUARY 8TH.

THE meeting at the Drill Hall on the above date was a very bright and beautiful one, the Hall being well filled with exhibits of more than average interest. There were flowers, fruits, and a few vegetables, quality throughout being high.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with Rev. W. Wilks, T. F. Rivers, J. Cheal, W. Poupert, G. W. Cummins, H. J. Veitch, A. F. Barron, F. Q. Lane, R. Parker, G. Reynolds, H. Balderson, F. Gleeson, J. Willard, W. H. Divers, G. Norman, J. Smith, G. Wythes, W. J. Empson, G. Woodward, W. Bates, A. J. Laing, C. Herrin, A. Dean, and J. Wright.

As will be seen there was a large attendance. The proceedings opened with a brisk discussion on a plan of the Council to form a mixed committee to inspect fruits, flowers, Orchids—everything—for the purpose of recommending medals. It met with such general disapproval that it was with difficulty that three members could be found who would consent to act. Eventually, however, the trio was found in Messrs. H. Balderson, G. W. Cummins, and G. Wythes.

Mr. John Watkins sent a dish of *Apple Lord Hindlip*, handsome conical fruits of excellent quality, which had previously received an award of merit, but now a first-class certificate was unanimously granted. Mr. J. A. Prall, Matfield, Kent, sent fruits of a sport from the well-known *Dumelow's Seedling*, or *Wellington Apple*, which it resembles in appearance, but covered with broken stripes of red. Cucumber "Everyday," sent by Mr. Owen Thomas, is a new and productive variety raised and grown in the Royal Gardens. Handsome fruits have been exhibited on previous occasions under the name of *All the Year Round*. An award of merit was recommended.

Mr. Empson, gardener to Mrs. Wingfield, sent well-ripened and brightly coloured fruits of *Chiswick Red Tomatoes*, and was awarded a vote of thanks. Mr. G. Woodward sent from *Barham Court* splendid fruits of *Passe Crasanne*, and a first-class certificate was awarded. A very old Pear, rarely seen in such fine condition. Pear *Bleekling* was sent by Mr. Allan from *Guntun Park*, medium sized fruits, very juicy and sweet, having a general resemblance to *Josephine de Malines*. Mr. J. Clarke, gardener to G. W. Keene, Esq., Mill Lodge, Barnes, sent a basket of *Mushrooms* (cultural commendation).

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, O. Thomas, J. T. Bennett Poë, H. B. May, R. Dean, J. H. Fitt, G. Stevens, W. Howe, J. Hudson, J. Jennings, C. J. Salter, R. B. Lowe, H. Selfe Leonard, J. Fraser (Kew), W. Bain, C. Jeffries, J. D. Pawle, G. Gordon, C. E. Shea, G. H. Engleheart, J. Walker, J. W. Barr, E. T. Cook, H. J. Cutbush, H. Turner, C. E. Pearson, H. J. Jones, and G. Paul.

A handsome group of well grown Ferns was arranged by Messrs. J. Hill & Son, Lower Edmonton. Some of the plants were small, while others were fine shapely specimens. Several of the leading kinds and varieties were represented, as well as a few that are more rarely seen. Messrs. J. Peed & Sons, Roupell Park Road, sent a number of flowering and foliage plants, comprising amongst others *Cinerarias*, *Cyclamens*, *Lily of the Valley*, *Cypripediums*, *Lilacs*, double *Daffodils*, *Cytisus*, *Aspidistras*, *Palms*, Ferns, and *Saintpaulia ionantha*. Mr. J. Russell, Richmond, was represented by a group of *Euonymus*, including both small standards and very dwarf plants, in the best of health. The same exhibitor also sent a basket of the handsome leaved *Andromeda Catesbaei*, and baskets of *Daphnes mezereum*, *atro-rubrum*, and the double white.

Camellias, both in the form of plants and cut blooms, were sent by Messrs. W. Paul & Son, Waltham Cross. The plants were well grown, and carried blooms of splendid form and substance. The varieties included *Marchioness of Exeter*, *Corallina*, *Double White*, *Mathotiana*, *Tricolor*, *Madame Eugène Massina*, *Donckelaari*, *Monteroni*, *Conspicua*, *Exquisite*, and the more rarely seen *alba simplex*. Considering the earliness of the season this was a splendid exhibit. Mr. J. G. Mowbray,

gardener to Major the Hon. H. C. Legge, Fulmer, Slough, staged a collection of *Freessias* in 5-inch pots. Individually the flowers were not very large, but the spikes were good and very numerous, and made not only a beautiful but a fragrant exhibit that was very highly appreciated by visitors.

Mr. G. Mount, Canterbury, sent a box of *Rose Catherine Mermet*, which for the time of the year was superb. The colour in some of the two dozen blooms was exceptionally rich. Messrs. R. & G. Cuthbert, Southgate, sent a number of pots of *Crocuses*, and some pots of a straw-coloured *Roman Hyacinth*. Mr. W. Camm, gardener to the Duchess of Cleveland, Battle, showed remarkably fine sprays of *Bougainvillea spectabilis* and *Bignonia venusta* in good form. Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, exhibited some very interesting hardy flowers, including early *Daffodils* in pots, *Iris histrioides* and *reticulata* in good form, *Hellebores*, *Primulas*, *Anemone pulsatilla*, *Crocuses*, *Galanthus*, and others.

Messrs. Paul & Son, Old Nurseries, Cheshunt, sent a collection of *Hellebores*, including amongst others *Councillor Benary*, *Gretchen Heineman*, *Olban Otto*, *foetidus*, *orientalis*, *lutescens*, *colchicus coccineus*, *orientalis punctatus*, *Colchicus guttatus* and *odorus*. From this firm also came *Saxifraga Boydi alba*, *Cyclamen Coum zonale*, *Hepatica triloba variabilis*, *Primula obconica lilacina*, and *Saxifraga lutea purpurea*, besides *Amygdalus Davidiana alba*, *Forsythia Sieboldi*, *Garrya elliptica*, *Amygdalus Davidiana rosea*, and *Alnus glutinosa aurea*.

A collection of *Primulas* came from Messrs. J. Veitch & Sons, Ltd., Chelsea. The major portion of the plants were not over medium size; but all were well flowered, and some exceptionally free. The colours of the flowers, which were of the refined type, were clear and distinct. The varieties were:—Doubles, white, blue, crimson, rose, salmon, and lilac; with singles, *Gigantic red*, *Gigantic Rose*, *Fern-leaf blue*, *Gigantic white*, *Chelsea Crimson*, superb fringed white, *Salmon (new)*, *Gigantic blue*, *Fern-leaf lilac*, superb fringed red, *Chelsea Rose*, and *Chelsea Blue*. Then there were the floriferous *Star Primulas*, and the now popular blue *Prim-roses*.

Messrs. Cannell & Sons, Swanley, occupied the whole of one side of a table with Chinese and *Star Primulas*. The plants were dwarf and sturdy, and producing large flowers on trusses of good average size. Particularly noticeable were *Lady Marsham*, *Lady Whitehead*, *Mrs. R. Cannell*, *Her Majesty*, *Victory*, *Dr. Nansen*, *Emperor Improved*, *Lady Emily Dale*, *Swanley Giant*, and *Swanley White*. Hardy flowers made a very interesting exhibit as sent by Messrs. Barr & Son, King Street, Covent Garden. There were lovely *Crocus* species, many *Hellebores*, *Lachenalias*, *Iris histrioides*, *Muscari*, hardy *Cyclamens*, and *Narcissus minimus*.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, de B. Crawshay, H. M. Pollett, H. Ballantine, H. Little, H. J. Chapman, W. H. Young, F. J. Thorne, W. H. White, E. Ashworth, J. Jaques, E. Hill, T. W. Bond, W. Thompson, Chas. Winn, S. Courtauld, and J. Douglas.

Mr. Miller, gardener to Lord Foley, Ruxley Lodge, Esher, staged a collection of *Cypripedium* insignis, the plants all being excellently grown specimens. Messrs. B. S. Williams sent a group of Orchids, comprising *Dendrobiums*, *Cypripediums*, *Celogynes*, *Laelias*, and others in splendid condition. Messrs. H. Low & Co., Clapton, were represented by some charming Orchids, in which *Odontoglossum crispum*, *Dendrobiums*, *Cypripediums*, *Laelias* and *Cattleyas* were conspicuous by reason of the shapely well coloured flowers.

Mr. W. H. White, gardener to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, sent a few bright Orchids, conspicuous particularly for quality. There were *Dendrobiums*, *Odontoglossums*, *Sophranitis grandiflora*, *Masdevallias*, and others. Messrs. J. Veitch & Sons, Chelsea, exhibited a collection, of which the chief features were the *Cypripediums* and *Dendrobiums*. These were of widely different forms and colours, but all alike were of excellent quality.

CERTIFICATES AND AWARDS OF MERIT.

Anthurium Dr. Lawrence (W. Bain).—An immense spathe, as broad as it is long. The colour is light salmon pink (first-class certificate).

Calanthe splendens (N. Cookson).—A handsomely formed flower of a bright rose colour (award of merit).

Laelia anceps waddonensis (J. Harris).—A lovely variety. The shape is almost perfect, and the colour pure white save for a blotch of yellow in the throat and purplish veins. The flowers measure $4\frac{1}{2}$ inches across, the depth being 4 inches (first-class certificate).

Phaio-Calanthæ grande (N. Cookson).—A bigeneric hybrid of which the sepals and petals are cream with a dull rose base. The brown lip is dull deep rosy red (award of merit).

[We have not received any list of honours which may have been awarded for exhibits of vegetables and fruit (not placed on the Committee tables) by six members of the Floral and Orchid Committees combined, and three members of the Fruit and Vegetable Committee. We consider this scheme of the Council the most revolutionary and unfortunate that has ever been formulated since these Committees were established. The sooner this fanciful scheme is abandoned the better for exhibitors and the Society.]

ANNUAL GENERAL MEETING.

As is customary, the annual general meeting of the Royal Horticultural Society was held in the Lindley Library, 117, Victoria Street, under the presidency of Sir Trevor Lawrence, Bart. There having been an exhibition in the Drill Hall earlier in the day, the number of Fellows present to hear the President's address on the report was very large—indeed the room was most uncomfortably full, there not being

seating space for everyone. It was certainly one of the best attended meetings that the Society has had for some years. At three o'clock precisely the meeting was opened by the reading of the notice convening the meeting and the minutes of the last annual general meeting, after which a considerable number of Fellows were elected. Messrs. G. Bunyard and H. Turner were elected scrutineers of the ballot, and Sir Frederick Wigan, Bart., and Messrs. J. G. Fowler and J. Hudson were elected in place of Messrs. N. C. Cookson, J. T. Gabriel, and J. Douglas.

The report and balance-sheet, given hereunder, were—and of which a copy has been sent to each member—taken as read, and the PRESIDENT, in moving their adoption, adverted to a few of the salient points. With brevity and clearness was the work of the year reviewed, and throughout the tone of Sir Trevor's remarks was of a congratulatory nature. The Jubilee year had proved a most prosperous and successful one in every respect, and in referring to the excellence of the fortnightly meetings a just tribute was paid to British gardeners, who, by their industry, skill, and disinterestedness, have done so much for the Society. Mention was made of the unfortunate lack of space in the Drill Hall, a circumstance which precludes the shows growing as they might and probably would do. This disadvantage, Sir Trevor continued, demonstrated the necessity of a Hall of Horticulture in our great metropolis, and suggested as a means to that end that every Fellow should increase his subscription from 1 to 2 guineas. Money was the desideratum in this matter, and if this were forthcoming the difficulty would be minimised, if not removed. The superb displays in the Temple Gardens were noticed, as was the fact that even for these the space was by no means sufficient, while the show of fruit the Crystal Palace was not forgotten. Chiswick as it was in the past and as it is in the present was commented on, and special stress was made in reference to the improvements in the structures which have been proceeding apace. Every effort was being made to maintain, or rather improve, the standard of Chiswick from an educational point of view, and the President thought the gardens were every year becoming more and more a credit to the Society. Continuing, the giving of certificates and awards of merit to new plants, with medals to larger exhibits, was referred to, and Sir Trevor expressed the fear that they were being too lavishly accorded, as the more that were given the more would their value be lessened. This he thought regrettable, and hoped that by making future selection more rigid, the value of the awards would be maintained instead of being reduced. Several other points were curtly noticed, one of the most interesting being the fact that the Fellows increased in numbers by 325. This, however, is somewhat put in the shade by the record that has been established at the last two meetings, when 113 members have been added. The financial position is excellent, as may be seen from the balance-sheet below.

SURGEON-MAJOR INCE made some remarks upon the report, which created a considerable amount of amusement, especially when the speaker ventured into statistics that were mainly wrong, as was promptly demonstrated by several Fellows. Dr. Maxwell T. Masters was quite to the point in his remarks when seconding the adoption of the report, which was carried by acclamation. Surgeon-Major Ince was more correct when proposing in eulogistic terms a vote of thanks to Sir Trevor for presiding. Mr. G. Wythes was the seconder, and it is needless to say the motion was passed without a dissentient voice.

Mr. ALEX. DEAN rose to draw the attention of the meeting to the innovation in granting medals which had been inaugurated at the Drill Hall that day, and which, he rightly observed, trench upon the Committees' legitimate work. The system that the Council had adopted was to select three members from each Committee, who amalgamating, proceeded to adjudge upon the groups. Apart from depriving the individual Committees of their proper duties, this system could not, for obvious reasons, be followed up successfully, and the speaker forcibly demonstrated this, and implored the Council to reconsider the matter.

Sir TREVOR LAWRENCE, in replying, said he thought it would be better if the chosen three from each Committee dealt only with exhibits of the particular Committee to which they were attached, and presumably this will be placed before the Council. But this system of choosing three members for the purpose has, as Mr. R. Dean pointed out, been in vogue with the Floral Committee for several years.

The proceedings, after some remarks by Mr. Berry of Faversham, were brought to a close.

REPORT OF THE COUNCIL FOR THE YEAR 1897-98.

The year 1897 will long be remembered as the Diamond Jubilee year of her Most Gracious Majesty, Patron of our Society—remembered, too, for the innumerable projects set on foot in celebration of the event.

In the report for 1896 the Council announced that they had no intention of adding to the number of projects by starting any ambitious horticultural celebration which would lay any strain upon the resources of individual Fellows. They stated that they proposed to establish a Medal of Honour in Horticulture, and that they had obtained the sanction of her Majesty to call it the Victoria Medal.

This proposal has been duly carried out; the medal has been prepared, and conferred on sixty recipients distinguished in various ways in our art and science; and it is believed to be the only medal associated with her Majesty's Diamond Jubilee, with the exception of the one founded by herself. It is, moreover, the only horticultural distinction in this country that is conferred for personal merit only, and is entirely unconnected with prizewinning.

By their action in this matter the Council consider that they have commemorated her gracious Majesty's Jubilee in a becoming and enduring manner; in a manner absolutely distinct from all other

celebrations; in a manner that lays no tax upon the Fellows of the Society; in a manner distinctly to the advantage and encouragement of horticultural skill and effort; and lastly in a manner which will carry down to all future generations of horticulturists the memory of Queen Victoria's long and happy reign.

Under the head of ordinary expenditure at Chiswick £1850 has been spent on the general work and maintenance of the gardens. Amongst other work, house No. 11 has been partially, and No. 10 entirely rebuilt, whilst No. 5, devoted to Peaches, has been raised in height and a new roof put on. All this work has been done by the Society's own staff of men. The receipts by sale of surplus produce amount to £357, making the net ordinary cost of the gardens £1493.

At Westminster, twenty Fruit and Floral meetings have been held in the Drill Hall, James Street, Victoria Street, and fifteen Committee meetings have been held at Chiswick, besides the larger shows in the Temple Gardens on May 26th, 27th, and 28th, and at the Crystal Palace on September 30th, October 1st and 2nd. Lectures have been delivered at seventeen of the meetings, exclusive of those given at the Crystal Palace. The number of awards granted by the Council, on the recommendation of the various Committees, has been as follows:—

Award.	At Provincial Shows.	Affiliated Societies.	On Recommendation of				Total.
			Fruit Committee.	Floral Committee.	Orchid Committee.	Narcissus Committee.	
Gold Medal	1	—	6	5	2	—	14
Silver-gilt Flora	5	—	—	40	8	2	55
Silver-gilt Knightian	2	—	16	—	—	—	18

Cultural Commendation	4	—	16	1	25	—	46
Total	36	80	119	50	251	20	1008

[Ninety bronze Banksian medals have been granted to Cottagers' societies.]

The Council must again express their opinion that there still appears to be a tendency to multiply unduly the awards recommended, and they earnestly request the several Committees to consider seriously whether there is not a real danger of impairing the value of these distinctions by such increase of their number; and whether it would not be possible, as well as politic, to be somewhat less generous in the recommendation of awards during the ensuing year. This is a question which the Council cannot but regard with solicitude, and they hope that every member of the Committee will consider that he has a real individual responsibility for the welfare of the Society in this matter.

On Wednesday, July 14th, the Council invited all the members of the several Committees to lunch with them at Chiswick, and to examine the Gardens. After the luncheon an address was delivered by Dr. Maxwell Masters, F.R.S., on the possibilities of an extended usefulness of the Gardens. A full account of the proceedings will be found in the Journal, vol. xxi., page 160.

The Council desire to draw the attention of all Fellows of the Society to the more extended use which the Scientific Committee might be to them if they availed themselves more freely of their privileges in submitting instances of diseases of or injuries to plants, caused by insects or otherwise. The Scientific Committee is composed of gentlemen qualified to give the best advice on all such subjects, either in respect to the prevention or cure of disease. The Committee is also glad to receive specimens of any subjects of horticultural or botanical interest.

The Council wish to express their thanks to the Director of the Royal Gardens, Kew, for allowing them to consult Mr. Massee, F.L.S., on the fungoid diseases, &c., brought before the Scientific Committee, and to that gentleman for his readiness in giving them the advantage of his knowledge and advice.

That Fellows, whether near or at a distance, may derive as much benefit as possible from their connection with the Society, the Council have recently appointed Dr. J. Augustus Voelcker, M.A., Consulting Chemist to the Society, and have entered into an arrangement with him whereby all Fellows, who are amateurs or *bonâ-fide* gardeners, may obtain at very small cost analyses of manures, soils, &c., or advice as to what description of chemical manure will be most suitable and profitable for application to any particular soil. The Council wish to draw particular attention to two points—viz.,

(i.) That Fellows desiring an analysis must follow explicitly and exactly the directions laid down in the book of Arrangements, 1898, and

(ii.) That Fellows who are in any way commercially interested in any artificial manure trade or horticultural business cannot claim Dr. Voelcker's assistance as Fellows, but if they wish to consult him must do so in the ordinary way of business.

The Society's great show, held (by the continued kindness of the Treasurer and Benchers) in the Inner Temple Gardens, was as successful

THE GARDENERS' ROYAL BENEVOLENT BALLOT.

I NOTE with some interest the remarks in your last issue by "A. D." on the above Institution, but I must confess that my feelings are by no means in harmony with his ideas when he says, "In that case signing would be needless, &c." Voting papers are sent out to all subscribers, and should be a reminder as to whether they have or have not paid their dues. People are forgetful in these matters, and it would be very hard for a willing person to be passed by for the sake of the cost of a reminder to give him that opportunity which would entitle him to his vote, and his signature is a guarantee that he is living and exercises his right in voting. If papers were allowed to be filled up without a signature, anyone might return them, and the rightful owner be quite ignorant of the fact; also you may have a fair number filled up after the owner was dead and the Committee know nothing about it. It is just as reasonable to say, "I have got another man's cheque and will fill it up, take it to the bank, and expect to get the money without his signature." I must confess that I fail to see in what way "A. D." is justified in describing the ballot "a sham one." I have attended two annual meetings, and have not seen the least cause to find fault with the way the business is conducted. What does he mean?

There is one thing in the voting that I think the subscribers to the Institution must have lost sight of—namely, the miserable support they

have given to one of their Vice-President's candidates. Of the forty-four candidates approved we must admit they one and all are worthy of our sympathy, and it is much to be regretted that the Institution is not in a position to give them that support they stand in need of. It is equally to be regretted that the whole of these candidates did not see the wisdom of supporting the Institution in earlier life. In glancing over the list of non-successful candidates we find two commenced to subscribe to the Institution at the age of seventy-four years, three at sixty-nine years, one at sixty-two years, and seven at the ages of fifty-one to fifty-eight years, and the others not at all, excepting in the case of widows whose husbands have subscribed, one eleven years, one nine years, one eight years, one seven years, and one one year. Of the above there must have been at least six that felt themselves on the doorstep of the Institution before they commenced to pay at all, and also found the Gardeners' Royal Benevolent Institution the only harbour of refuge to keep them out of the workhouse, and by paying two or three pounds they would have a claim on the Institution for so doing, and their benevolence points to themselves, as they could only hope and expect to have their money returned a thousandfold.

We are all glad to sail into any port in a storm, and doubtless that must have been their feeling, but if the Institution were dependent on the like of these subscribers and non-subscribers it would quickly vanish, hence the question arises, Who are the mainstay and backbone of the Institution? Why, the donors, who hand over their money, knowing

they will never be an incumbrance to the Institution. Consequently it is principally from them and them alone that the Institution is able to exist, and this is a fact that should not be lost sight of. Although every candidate commands our sympathy, and that in the strongest form, still we naturally lean most to those we personally know and can truly sympathise with, and of those in the last election I know only one, Wm. Freeman. This man has been known by my employer for over forty years as a hard working, honest, deserving man. He was in his last place thirty-nine years. His employers and all their family are dead, every one of them. His brother, for many years manager to Messrs. F. & A. Dicksons, Chester, is dead, and his other brother, for many years gardener to the Right Hon. the Earl of Derby, Knowsley, is dead also. He invested his money in a business in the hope of getting a living in his declining days, but has lost the whole, and he now finds himself on the world almost without a friend.

My employer said, "This is a very proper case for the Gardeners' Benevolent, as he comes within the pale of their constitutions; bring him forward and see what you can do." He was duly nominated, and his case canvassed in the usual way, supported by a Vice-President, with a result that in three years 1425 votes were recorded in his favour—i.e., including my employer's own votes. In glancing over the list of subscribers, other than those who are nursery and seedsmen or derive their livelihood from gardening pursuits, how many are there who have supported the Institution with a more liberal hand than my employer has, and who has received less support? I ask this question in the interests of the Institution, and not from any selfish motive. In 1866 he gave £105, and has since subscribed 21s. a year. In 1867 he gave £52 10s. for his son, then a youth in college, and in 1889 he gave £10 10s. for his grandson, then a little boy: total £168. Surely such a donor deserves more support than he has received. In contrast with this I will quote an instance that occurred a few years ago.

A railway porter lost his wife and left him with several children, one being deaf and dumb. I suggested to the porter that he should get this child into an institution, to which he agreed, and I appealed to my employer for help, and he at once said, "Oh, yes; I am connected with an institution that I have supported very liberally for many years, and as executor to a friend have £1000 to hand over in a day or two, but she has only one chance, as she will then be too old. However, I will tell them this is my candidate, and shall expect her put in, or will turn my back on them, as I will not risk a defeat." The child was sent for; hence the power of a liberal donor; and who has more right in the selection of candidates? How very different in Freeman's case. Here is a Vice-President of the Institution given £168, and he does not receive support that is accorded to a few subscribers who have thrown down at the doors of the Institution a few pounds in the last years of their independency, so as to enable them to say, "Being a subscriber I expect your votes."

What a recompense to a Vice-President who has supported the Institution so well, and how encouraging to other gentlemen to become Vice-Presidents! Were it me I would, with all respect, request the Institution to pass a wet sponge over my name, as a more suicidal thing I never knew. If this is calculated to benefit the Institution the sooner I am a stranger to it the better. If the name of a Vice-President is a guarantee as to the genuineness of an institution it should be an equal guarantee that a candidate is worthy of support.—J. OLLERHEAD, *Wimbledon*.

GROWING POTATOES WITHOUT TOPS, AND PREPARING TUBERS FOR GOOD CROPS.

I WAS much interested in reading Mr. D. Thomson's remarks (page 83) on "A Curious Way of Growing Early Potatoes." In the garden where I was first employed early Potatoes were grown for use at Christmas and onwards by an old man who was gardener there until a few months previous to the time I began work, when he died and was succeeded by his grandson.

I heard that they were grown by breaking off the shoot of the Ashleaf variety, and that if the first shoot was broken off the Potatoes would not shoot again, but throw out tubers instead.

In my younger days many people in Dorsetshire firmly believed that the old Ashleaf would not grow if the first shoot was broken off, and some old men in the village were surprised to hear of a dairyman who came from a distance making it a rule always to rub off the first shoots of his Ashleafs, and to lay them out to form a second growth from which he depended on getting a much better crop.

The "grandson" above mentioned was not successful in procuring Potatoes in the same way as his predecessor, and I have wondered very much how they were grown. It is only about three weeks since I was talking about it, and saying the old gardener had a secret for growing Potatoes early that no one else seemed to know anything about.

If I am not mistaken those were grown outdoors, and covered with ridges of ashes: but be that as it may, the new tubers were adjoined to the old the same as we sometimes see small tubers growing on a dry or partially decayed one when stored for the winter, and were, I should think, about the size on an average of a large Cobnut. Do not you think it quite possible that the "old man's" new Potatoes were grown as described by your correspondent, Mr. Thomson?—SOMERSET.

[We know that by persistently suppressing the growth of tubers of Early Ashleaf, and planting such tubers, or placing them in boxes with soil, that they will supertuberate, but the progeny is very small. Large tubers of later varieties prepared as described by Mr. Thomson afford

very much larger "new Potatoes" at Christmas and onwards. As to the first and second shoots of the Ashleaf variety being removed or retained, when the tubers are heaped in a rough and ready way in a dark warm place, they will have sprouts like straws that fall off with the slightest touch. They are of no use, and the second growths from the tubers made in a light position are much better; but the best plan of all is to winter the tubers thinly in a light, cool, frost-proof place, and let the first growths develop steadily and sturdily, and be affixed so firmly as not to be easily displaced. Most gardeners can find suitable positions for preparing in shallow boxes the planting tubers of their first earlies. A labourer suspends his boxes from the ceiling of his back kitchen, and we think our racy correspondent, Mr. W. Pea, could cite a case where the cost involved in making provision for preparing the tubers in tons has proved a wise investment, as resulting in earlier, heavier, and more valuable crops grown by the acre for the London market; but whether he feels at liberty to do so we do not know.]

A LITTLE MIXTURE.

TEN MINUTES' NOTES.

LAST week I confined my notes to conservatory climbers; this week the following subjects have entered my mind, and almost in an involuntary way run from my pen, for I do my jotting first, and write my little introduction last.

CENTAUREA CANDIDISSIMA.

This is not so much grown now for bedding purposes as formerly, possibly on account of it being somewhat miffy to propagate. We use about 400 plants, principally as an edging for four large beds of the now old-fashioned Tom Thumb "Geranium," and they are very effective. The beds were originally laid out from a design of the late Mr. Ingram of Belvoir, and have a permanent edging of Box a foot high, and next to this greenery, with the mass of scarlet behind them, the Centaureas show to advantage. I am usually successful, or perhaps fortunate, in raising sufficient Centaureas for the requirements of the beds, and will briefly describe my method of increasing the plants. Wet summers are rather unfavourable for the production of good cuttings, as the growths are apt to be too sappy. In this case they are better cut and laid on the potting bench for a day to dry somewhat. Select the thinnest and most wiry cuttings, and with a sharp knife take them off with a heel; trim each heel cleanly, remove with the hand the lower leaves, at the same time rub off as much of the woolly covering with the thumb and fingers as possible with discretion, finishing by shortening the tips of the leaves. Insert about eight of these in a 6-inch pot, filled with a mixture of two parts loam to one of leaf soil, and a good sprinkling of sand; well crock the pots, and make the soil quite firm, using dry sand on the surface, so that a little falls into the holes with the cuttings; well water them in, and plunge in ashes to the rim in a cold frame in a north aspect. Keep close until rooted, then remove to cool vinery, water very sparingly, pot off in spring.

SPROUTING POTATOES.

Although an advocate of setting on end a few early Potatoes for frame work or early borders, I have yet to learn the wisdom of thus packing the tubers months before they are needed for planting, whereby they exhaust their vitality, the tubers looking like shrivelled mummies with abnormal growths of 2 inches and the box full of cobwebby roots. I contend this is against Nature, and must lead in many cases to disappointing results. The chances are that when these sets are put in the ground the roots will perish, and then fresh ones must of necessity be produced before the shoot can be sustained; and, moreover, should the weather be cold and wet, decaying of the sprout is inevitable. A medium sprout is much better. A month is long enough to allow this to be attained when the tubers are set on end in a cool place, and they are then not exhausted. I find it a good plan to well bake in the sun all early seed Potatoes after they are taken up by placing them on a hard path for several days, moving them over from time to time to become well greened. They rarely take the disease after that process, and will stand more frost. When coming through the ground the growth from these ripened tubers is always firmer and tougher—i.e., not nearly so succulent and tender as those from unripened tubers, and these may be damaged by a slight touch of frost, which the others resist. Another point is worth mentioning. Vermin have an aversion to these greened tubers, and will not touch them so long as they can find others more suitable to their palate.

AGAPANTHUS UMBELLATUS FOR PERMANENT BEDS.

An outdoor bed of this Liliaceous plant is somewhat of a novelty, but there is no reason why it should not be more generally so employed, especially in the southern counties, where it may be planted in clumps in the nooks and warmest corners of the hardy flower garden. We have only a small bed of them here, and in the rather exposed position the plants flower very well. They prefer a strong loam, with decayed manure, and some sharp sand to keep the soil porous, plenty of water in summer, and a covering of fallen leaves during winter to preserve them from severe frost, or excessive moisture when at rest. This covering should be removed gradually to allow an easier transition to the elements of light and air. After being removed altogether, a dressing of decayed manure, pointed in with care, benefits them. In genial summers they flower during September. This plan may be well worthy a trial by those who have several large pots of Agapanthus over their requirements.—GEO. DYKE, *Stubton Gardens, Newark*.

PRESENTATION TO MR. R. PINNINGTON.

THE annual general meeting of the Liverpool branch of the N.A.G. Association was held in the Common Hall, Hackins Hey, Liverpool, on Thursday last, W. Histed, Esq., presiding over a good attendance of members. A notice of motion had been placed on the minutes in the name of several members to either break up or re-arrange the Liverpool branch, but this had been withdrawn, and wisely so, judging from the splendid report read by the Secretary. The Treasurer's report showed a balance of nearly £10. The newly elected President is J. H. Drake, Esq., and Messrs. H. A. Robins, Treasurer; J. M. Smyth, Secretary; A. Cooper, Assistant-Secretary; D. W. Cangle, Exhibition Secretary; and Messrs. Glover, Gillanders, and Pearce were added to the list of Vice-Presidents. Several handsome contributions were promised to the prize fund.

The Secretary, in the unavoidable absence of the President, Isaac C. Glover, Esq., said he had a pleasing duty to perform—viz., to recognise in some tangible form the continued support given to the branch by Mr. R. Pinnington of Roby, who by his kind manner and ready assistance as adviser, lecturer, adjudicator, and in many practical ways had endeared himself to all members. For himself he could only speak in the highest terms of Mr. Pinnington's ability and friendship, and he was quite sure that every member was the better for having known Mr. Pinnington. He had great pleasure in asking Mr. Langley to present Mr. Pinnington with a handsome travelling bag, with initials engraved. Mr. Langley said that the compliment was thoroughly deserved, and trusted that the recipient would be long spared to use the bag, also to continue his good work amongst them. Mr. Pinnington, in reply, thanked all very much for their kind appreciation of his work, which he assured them had been willingly given. In no profession was there more scope for one's abilities, or greater gain to mind and body, than the delight of cultivating plants and flowers. The value of his work would have been amply repaid by the kind record in the minute book, but as the Committee thought differently he could only thank them again for their handsome present, which would always be highly valued. The usual votes of thanks closed the proceedings.

THE YOUNG GARDENERS' DOMAIN.

POTTING AND WATERING.

THIS is a subject upon which a large volume could be written without exaggerating its importance. Where good plant culture is desired it is essential for this work to receive strict and careful attention. It forms part of the young gardener's duties for the whole of the year, and what a credit it must be for each one to show his chief that he is not careless in this matter. In many cases the plants under his charge will soon show whether they are receiving proper attention or not. If the young gardener is at all interested in his work he will not be satisfied unless good results follow and the plants repay him for the little extra attention he has bestowed on them.

The main object of all gardeners should be to do everything just at the proper time. If any plant is worth growing at all it should be worth growing well, and at no period must it be neglected, or good results cannot be expected. Spring is the busiest time for most gardeners, and a few hints on potting may prove helpful to young readers of the "Domain." Always use clean and dry pots, which must have thorough drainage, with clean crocks of various sizes. A large piece, with the concave side downwards, should be placed at the bottom of each pot, and a few smaller pieces over it, the quantity of drainage being decided by the size of the pots. Over this a thin layer of moss or rough fibrous loam is placed to prevent the soil from getting among the drainage.

The next thing is to prepare the compost, which should always be of the same temperature as that in which the plants have been previously growing. Both pots and soil ought invariably to be prepared before the plants are brought in. This being done we may proceed with the work and carefully turn out the plants. Remove the crocks and all loose soil around the roots, and if they are matted together it is advisable to open them out. A handful of compost should be put at the base of the roots and made firm. In most cases pot firmly with the fingers alone, as the potting stick is the cause of much injury done to the roots, especially with tender-rooted plants. I find it advisable to dispense with it altogether in many cases, but with such plants as Chrysanthemums, Azaleas, Camellias, Strawberries, and others, it is impossible to repot without it. It should never be put near the roots, and when used the operator must be careful not to injure the roots by ramming too severely.

After potting, the plants should be kept close until root action has recommenced. Well shade from the hot sun, and keep a somewhat moist atmosphere by gently syringing the plants or between the pots. In my opinion this is the most important time for careful watering. The plants should first of all be given enough to settle the soil, but no more until they really require it. The method by which many gardeners are able to know when a plant is dry is by tapping the pots with the knuckles, but I have found this method of examination will not suffice in many instances. It is always best to test plants which require the most careful watering by lifting them, when one can quickly feel if they are heavy enough for the size of the pots. In winter all plants require to be kept somewhat on the dry side, particularly those in greenhouse temperatures.—J. F. D., *Yorks.*

MUSA CAVENDISHI OR BANANA.

It is not my intention to write regarding the note on Bananas on page 35 of the Journal, but it is seldom we see this delicious fruit mentioned in gardening literature. The plentiful foreign supply, and the expense connected with their cultivation at home, seeing they need more heat and room than can be spared in most places, are the reasons why they are so seldom seen growing. I enclose a photograph of a bunch of fruit which was taken about the middle of December last, the first fingers of which were ripe on the 8th of January. The plant was from a sucker detached during the spring of 1896, and grown in a 15-inch pot. The plant was used in the mansion for some time instead of a palm, and was never at that time intended to be utilised as a fruiter. As a plant in the bed where they are grown for fruit was making little progress, it was taken out and this plant put in its place during March of last year. I think the photo will show that the fingers are a good size, and in all there

FIG. 20.—MUSA CAVENDISHI.

were 187 fully developed on the bunch. An opinion of the photo will be gladly received, and if it is considered worthy of reproduction all the better.

I am of opinion that an ordinary stove temperature during the dull winter months is most suitable for Bananas, raising it with the increased sunshine in the spring, when they grow very rapidly. They get plenty of top-dressings of horse and cow manure, besides being watered with sulphate of ammonia dissolved in the water. I never had anything to do with Bananas till a little over a year ago, and I would be thankful to anyone who has had experience with them, whether belonging to the Y.G.D. or the elders in the profession, for information regarding them, especially with respect to temperature.—S., JUNIOR.

[After its sojourn in the mansion the plant seems to have done very well. Well-ripened home-grown Bananas are much superior to imported fruits, which have to be cut in a green state.]

THE TUBEROUS BEGONIA.

THE tuberous Begonia has of late years become very popular, and deservedly so, considering its easy culture and the various uses to which it can be adapted. It is a charming plant for summer bedding, and I will treat on the culture of the plants for that purpose. Unlike many older plants which require so much house room and attention during the winter months, the tubers can be stored away safely until again needed. The present month is a suitable one for sowing seed if the plants are required for this season's bedding. Pans or boxes should be well drained

and filled with a compost of one half leaf soil, the remaining half sweet loam and silver sand, well mixed and finely sifted. Press it moderately firm and leave it quite level on the surface. Give a thorough watering through a fine rose can, allowing the soil to drain for a few hours, when seeds should be sown on the surface, taking care to scatter them evenly, or when the seedlings appear it will be detrimental to them if they are thickly placed. Cover the pans with sheets of glass and plunge them in bottom heat, shading them with moss or paper. Excessive evaporation from the soil is to be avoided, the object being to keep it moist and sweet so that the seeds will germinate quickly.

Subsequent watering must be done by holding the pans up to their rims in a tank or bucket of tepid water. In this way the water, ascending through the drainage, will moisten the soil throughout, and the seedlings will not be washed out of place. Gradually expose them to the light and air by tilting the glass, but shading from the sun will be necessary. As soon as they can be handled prepare other pans or boxes as before advised, and lift the plants carefully with a small forked stick, pricking them off an inch apart. Continue to keep them in a moist temperature of 65°. In the course of a few weeks they will be large enough to handle, and may be planted 3 inches apart in other boxes or potted in 60's. The soil should consist of loam and leaf soil in equal parts, with plenty of sand. Keep the plants close and shaded until growing freely, afterwards giving them more air and near the glass.

Much care and attention is saved by planting them 9 inches apart each way in frames, and when established giving more air and light shade during the hottest part of the day. They are much injured by drought, hence strict attention must be paid to watering. Gradually harden them, and plant from 6 to 9 inches apart, according to size, in beds of rich soil. When they have done blooming lift them with as much soil as possible, lay them in boxes, keeping each colour separate, and place in airy sheds to mature, ultimately shaking off the soil, removing the stems, and storing for the winter in shallow boxes, covering them with cocoa fibre. It is advisable to examine them occasionally when in flower, and those not true to colour should be lifted out or labelled, so that when used for bedding the following season they will not be mixed.—
NIL DESPERANDUM.

(To be continued.)

HARDY FRUIT GARDEN.

Planting Fruit Trees and Bushes.—Under favourable weather conditions—namely, mild, dull, and dry—all kinds of fruit trees and bushes may be planted with reasonable hopes of successful growth following. The really best period for planting is late October and during November, but through the occurrence of wet periods or other obstacles in those months the work may have been delayed. When that is so, advantage must be taken of every favourable opportunity that may present itself during the next few weeks.

The chief points of importance in planting are to carry out the work only when the soil is dry on the surface, and works cleanly. It is better to wait for these conditions, even if the planting is deferred later, than to carry out operations in soil that adheres to the tools. The roots of trees and bushes, of whatever size, ought not to be exposed to the air longer than is necessary to admit of jagged and broken ends of roots being pruned smoothly. All trees and bushes should have the roots laid-in in moist soil as soon as received from the nursery, and only lifted as wanted for planting. Endeavour to have the soil well prepared by previous trenching or digging, but not heavily manured. Ground enriched for a previous crop, which was not of an exhausting nature, is suitable for fruit. Soil that requires manure, owing to its poor character, ought to have it well decayed and thoroughly incorporated.

Make shallow but wide excavations for the reception of the roots, in which they can be spread out to their full length, placing them on slightly convex mounds of soil. Arrange the roots in layers, covering each with a little prepared soil consisting of loam and wood ashes, spreading it upon the fibres outward from the stem. Trees which will require support stake at once, protecting the bark from injury. Spread over the roots a layer of light manure.

Unless young trees are well furnished with masses of fibrous roots, and are transplanted with adhering balls of soil, shortening the branches must be resorted to, for a tree with an insufficient number of roots is not capable of supporting long branches. Hence it is necessary in such cases to prune back to strong wood buds. Trees with a small number of branches, and requiring more to furnish them well with a good foundation, must also be shortened, so that vigorous growths may push in the positions desired. Also, if the upper or terminal buds of Apples and Pears are flower buds, the shoots must be pruned back to wood buds for securing the necessary new growth. The pruning may be carried out when the buds commence swelling.

Planting and Pruning Raspberries.—The present is a suitable time to make fresh plantations of Raspberries. No crop should be expected from them during the present year, but the stools ought to be encouraged

to make free and strong growth in order that fruit may be produced abundantly the following year. The soil for Raspberries must be prepared deeply, and liberally manured in the course of digging or trenching, good half-decayed farmyard manure being the best application. Plant a trio of young suckers with bushy roots, in clumps a yard apart, in rows 4 to 5 feet asunder, the canes to be trained to stakes eventually. They may also be planted 18 inches asunder in rows 4 feet apart. A substantial trellis of wire 5 feet high must be fixed, to which the canes may be trained at equal distances.

It is desirable that all canes newly planted be cut down to within 9 inches of the soil. This prevents fruiting, but encourages growth. After the planting is completed, mulch between the plants with a layer of manure.

Preparing Soil for Strawberry Planting.—Ground intended for Strawberries to be planted this spring ought now to be well prepared. Spread upon the surface a liberal dressing of decayed manure, digging the ground deeply, and breaking up lumpy portions. If of a poor, shallow character the subsoil should be manured and loosened, but not brought to the surface. This may be best effected by bastard trenching. Soils of a very heavy or adhesive character are difficult to prepare without adding material of a lightening nature. Burnt refuse worked into the surface is very beneficial.

Established Strawberry Beds.—When cleaned and mulched in autumn Strawberry beds seldom require attention before the commencement of growth in spring, when the undecomposed remains of the autumn mulch may be raked off, and old withered foliage trimmed away. The soil will be better for a short period of exposure, after which apply a mulch of fairly fresh strawy material, previously cutting away withered foliage, and dressing round the crowns with soot.

Young Strawberry Plantations.—Hoeing between the rows of young plants in dry weather is the best cultivation which can be given at the present time. The process admits the air, assists in the pulverising of the soil particles, warming the ground, and releasing plant food. Growth is thus promoted, and the vigour of the plants insured.

FRUIT FORCING.

Figs.—Earliest Trees in Pots.—The trees set to work in November or early December for affording ripe Figs in April and May are sending out fresh roots plentifully, the bottom heat being kept steady at about 70° to 75°. Bring up the fermenting materials to the rim of the pots, and instead of allowing the roots to come over the top check them by placing pieces of good turf round the rims to induce plenty of fibres close to the stem and secure a sturdy habit. Provide moisture in the atmosphere by syringing twice a day and damping the paths as may be required in bright weather. Admit a little air at 70°, increasing it with the temperature; close at 75°, but lose no opportunity of maintaining a heat of 80°, 85°, or even 90° from sun influence, as that is very advantageous in the early part of the afternoon. Supply water abundantly at the roots whenever required, always before the trees are distressed for want of it, ever using a mild stimulating and sustaining food in thorough solution in it, and always weak and tepid. Let the temperature in dull weather range from 60° to 65°, 55° to 60° at night when the external air is very cold, but 5° more when mild. Disbudding will need attention as growth advances, and gross shoots require stopping, but the finest Figs are borne upon extensions. Shoots, however, should be pinched where necessary at the fifth or sixth leaf to prevent a straggling habit, but avoid crowding the trees with foliage, keeping them sufficiently open to admit light and air to every part.

Early Forced Planted-out Trees.—The trees started early in the year are progressing very satisfactorily, the night temperature having been raised to 55°, and to 60° or 65° by day from fire heat, with an advance from sun heat and free ventilation to 70°, or even 75°. Syringe twice a day as before advised, but in dull weather damping the paths with an occasional syringing will be all that is required. See that the borders are properly moistened. If the trees are weak, a thorough supply of liquid manure, not too strong, and tepid, will assist the growth and root action, which must be encouraged by surface dressings of rather lumpy material, but not thick, an inch or two thickness being ample.

Vines.—Eyes and Cut-backs.—Eyes may now be inserted, using pots, pans, or pieces of turf. Select firm, well-ripened wood, filling the pot or pan with sound friable loam, inserting the buds with a pinch of silver sand half an inch beneath the surface, plunging the pots in a bottom heat of 80°. Cut-backs should be placed in a house where they will have a temperature of 60° to 65° at night, and 70° to 75° by day. When they have started into growth shake them out and return them to the same size of pot, using good friable loam, providing a moist and rather close atmosphere until they are re-established, when they should have a position near the glass, so as to insure sturdy, short-jointed, thoroughly solidified growth.

Early House.—The Vines in flower must have a temperature of 65° to 70° at night, 5° less on cold nights, and Muscats 70° to 75°, rising 5° to 10° by day with gleams of sunshine. Keep the atmosphere somewhat drier by free ventilation, leaving a little on at night; yet a genial condition of the atmosphere must be maintained by sprinkling the floors two or three times a day during bright weather. Any shy-setting varieties may have the pollen distributed by means of a camel's-hair brush. Stop the laterals at the first leaf, and keep those pinched to one leaf throughout the season; but growths beyond the bunch may be allowed to make two or more joints, provided there is space for the full exposure of the foliage to light and air. Avoid overcrowding the foliage. It is better to reduce the laterals than retain them to the extent of crowding, retaining fruit

in proportion to the amount of foliage. Heavily cropped Vines make correspondingly little foliage, and the Grapes frequently do not colour because there is not sufficient stored matter for conversion at the time of ripening into the essential purple or gold colour. Reduce the crop when necessary so as to have some growth in the laterals, thus keeping the roots active, and thereby maintaining a good supply of nutriment judiciously applied as top-dressings or in liquid form.

Vines Started at the New Year.—The Vines are in leaf and showing for fruit; but let this be clearly visible before disbudding, removing the weak and least promising growths in the first instance, then give further attention when it is seen which shoots are likely to afford the best bunches.

Vines to Afford Grapes in July and August.—The Vines must now be started. They break most evenly and strongly when assured a moist genial atmosphere, therefore damp the rods three times a day, and sprinkle other surfaces. Avoid, however, keeping the rods constantly dripping with water, for the tendency in that case is to cause the emission of aerial roots, which are unsightly, if, indeed, they are not prejudicial in appropriating the stored-up food, which otherwise would be expended in the formation of roots in the border, or go towards invigorating the growth. A temperature of 50° at night, 55° by day, and 65° from sun heat is suitable until the buds begin to move. Bring the inside border into a moist, but not sodden, condition by repeated waterings, following with liquid manure if the Vines are weak. The soil has a strong affinity for the manurial elements, grasping and retaining them for appropriation by the roots as required. Afford outside borders sufficient protection to prevent chill, a little partially decayed material supplying all that is required. Eschew thick coverings of manure, particularly when likely to fall into a close soapy mass, giving preference to lumpy material, which will admit of the free access of air.

Late Houses.—The Vines being cleared of Grapes early in January, the borders top-dressed, and everything then put straight, a start may be made without much further delay, as it is essential that the Vines have the full benefit of the summer, and perfect their crops not later than the middle of September. Keep strong rods in a horizontal position, and insure an even break by sprinkling them occasionally. Let the temperature be kept at 50° to 55° at night, and on dull days, until the buds move, then allow 5° to 10° more by day, and an advance of 5° or more from sun heat, but lose no opportunity of ventilating freely.

Ripe Grapes.—Avoid fire heat as much as possible in the Grape room, admitting air to prevent an accumulation of moisture, replenishing the latter with clear soft water as required. An equable temperature of 45° is most suitable.

New Borders.—The compost for new or renovating old borders should be prepared; the top 3 inches of a pasture—rich, friable, and neither light nor heavy—is most suitable. Red soils are best—that is, those of the old or new red sandstone, as they contain iron, which influences the health of the Vine and the colour of Grapes. About twelve parts loam, two parts of lime rubbish, a similar quantity of charred refuse (termed wood ashes), one part of fresh horse droppings, and a tenth part each of crushed bones and soot—the bones by weight and the soot by measure—mixed, gave the best results we have seen in Vines, for both home use and market.

Provide a foot of drainage, rough at the bottom and road metal size at the top, placing on a couple of inches thickness of clean (free from pieces of wood) old mortar rubbish, and take care to have drains under for carrying off superfluous water. A width of 4 to 6 feet is ample to start with, and 2 feet 6 inches depth of soil suits the strong sorts, including Muscats. The materials will settle into about 2 feet depth, and the roots can be kept up by top-dressings. The proper or a good time to plant Vines is from the buds swelling to the shoots being an inch or two long, then shaking out and laying the roots out as straight as can be done without injury. Vines raised from eyes can be planted up to June, turf-raised being the best, but those in pots answer, only do not allow root-binding.

THE BEE-KEEPER.

LARGE versus SMALL HIVES.

IN bee-keeping, as in everything else, there are differences of opinion. This is an advantage, as it is not well for all to keep on the same beaten track and not make experiments. If we did so very little advance would be made. Before giving up our well-tried methods which have answered so well in the past, we should ask ourselves the questions, Will it entail more labour in the apiary? shall we obtain a larger surplus? and will it be as beneficial to the bees? This is of great importance, as our honey harvest does not last long, and whether the weather is favourable or not, the flowers will bloom in due season and fade away, and it is only those colonies which are in good condition that are able to store a surplus. This is observed more in an inclement season than when the weather is fine and bright the whole of the time.

For this purpose, which is the better? a large hive, or one of small dimensions? It is as well to understand the difference, as a correspondent lately condemned a hive of certain dimensions as being too small, whereas it was much larger than the hive recommended by him. A large hive when supered should contain at least 4500 superficial

inches of storage space, including the brood combs. The hive must be crowded with bees; not only a few stragglers on the outside combs, which an inexperienced bee-keeper would probably term a hive full of bees. If the quilt is only partly lifted from the top of the frames the bees at once boil over the sides of the hive; they are then in prime condition for storing a surplus, and it is surprising what a colony of bees of this description will do during the honey flow if the weather is favourable for only a few hours.

A small hive may contain 1500 superficial inches, less or more, a few inches either way is immaterial. It is sufficient for our purpose to show the vast difference existing between the two, and illustrates the necessity of giving the dimensions of hives, or the number of superficial inches of comb they will contain when full.

It is no uncommon thing to find hives still in use in many parts of the country as small as the above mentioned hive without any means of enlarging it. It is satisfactory, however, to learn from several correspondents that these small hives are doomed, and that the more rational system, as advocated in these pages, is being followed.

THE DOUBLING SYSTEM.

Having shown the difference between a large and small hive, we will explain the system of doubling, which has been mentioned on more than one occasion in these pages, and after another year's experience of this system, we are more than ever convinced of it being the best adapted for use in this country.

What is doubling? This may not be the best term, but it is the one most commonly used. The inexperienced, however, may be led astray by the word, as the hives are really not doubled in the sense that some bee-keepers may take it.

"Doubling" takes its name from the fact that another hive or box is placed on the hive containing the bees and brood nest. This hive, which may be termed a super, is of the same dimensions as the bottom hive.

The frames, all being of the standard size, are interchangeable one with the other. It is important that all the frames in an apiary be of the same size (not necessarily of standard size). There is then much less labour in the general routine of work.

To be successful in the management of bees the necessary work must be done at the right time. If extra room is required in a strong stock to-day it should be provided for them at once; not delay doing it for a few days, or it may be a week.

By the end of May, or a week or ten days later according to the weather, many of the hives will be crowded with bees, and be in good condition for doubling. We prefer doubling those stocks which are headed by a young fertile queen hatched the previous year. The middle of a fine day is the best time for the operation, as many of the adult bees will be on the wing, and it will be much easier to find the queen than when the bees are all in their hive. Examine each comb as it is lifted from the hive until the queen is found. The frame, with the queen and adhering bees, must then be placed on one side, care being taken that the queen is not shaken from the comb whilst handling it. An empty hive or a frame stand is a useful adjunct in an apiary; there will then be no danger of crushing the queen or bees.

Lift out four or five of the frames containing brood and place them on the top storey with the adhering bees, fill in vacant space with combs that have been stored away since the previous year, or with comb foundation, placing the frame with adhering queen and bees in the middle of the hive.

USING QUEEN EXCLUDER ZINC.

Place a sheet of queen excluder zinc over the top of the frames. This will keep the queen and the drones in the bottom hive, the workers only being able to pass through. The top storey may then be placed in position, and if the colony is a very strong one the empty space may be filled with clean old combs. These are tough and will not break down in the extractor, as new combs are liable to do. If the bottom hive holds ten frames, not more than nine frames should be placed in the super. This will allow them to be spaced wider apart, causing the bees to make the cells deep and more honey to be stored.

If the hive has not sufficient bees, and the honey flow is expected in three weeks, take a few frames and adhering bees from another colony, for preference one having an old queen. The frame containing the queen with adhering bees should be placed on one side, as advised with the other hives, and the combs and adhering bees placed alternately with the others in the top storey of the hive operated on. Being the middle of a bright day many of the adult bees will be on the wing, those on the comb will be chiefly young bees, and will not fight, and if quietly handled not a bee will be lost.

Bees at that season may be mixed indiscriminately by allowing them to remain on their own combs and placing them alternately with the bees in another colony. Some of the old bees will return to their old home, but many will remain in their adopted quarters.

It is impossible to make a colony of bees too strong at the time of

the honey harvest; more particularly is this observed when they are worked on full-sized frames for extracting purposes as above, as they are fully under command, and will store a surplus whilst weak colonies would starve.—AN ENGLISH BEE-KEEPER.

LARGE FRAMES.

ON page 113, "Warwick" says, "Will 'George Howdenshire' kindly inform one who is just commencing bee-keeping where to obtain the frames he mentions on page 70, 20 inches by $8\frac{1}{2}$, also the size of hive he would most recommend?" In the first place I may tell "Warwick" I am not the originator of the large frames: so far as I know they were made first in Scotland. If "Warwick" has the back number of this Journal for June 7th, 1894 (page 462), he will find it recorded that Mr. William Cowie had hives with fifteen frames 20 inches by $8\frac{1}{2}$, and two tiers of supers filled by the 31st of May. I do not know any dealer who sells these frames. The bee-keepers in this district either make their own or get them made by a local tradesman. What hive do I most recommend? I may state that several hives have been tried here—viz., the hive to take ten standard frames: Mrs. Simmon's hive that takes a frame 16 by 10 inches; the Scotch hive, as I prefer to call it, that takes frames 20 by $8\frac{1}{2}$ inches, and another that takes frames 18 by 9 inches. Of the two latter it is hard for me to say which I prefer, as the results have been so good in both cases. The only drawback to the hive that takes 20-inch frames is the large supers are not so easy to manipulate. However, to a beginner I do not hesitate to recommend the hive that takes twelve frames 18 by 9 inches. The hive to take these frames is $18\frac{1}{2}$ by $18\frac{1}{2}$ inside measurement, single eased, made of five-eighth wood if used in a bee house. Such hives do well in an outside apiary. Six miles from my home, in a good Clover district, three of us are interested in a bee house that holds twenty hives, arranged to face N., E., S. and W. The hives have single cases, are not so clumsy as some might think, and manipulation at all times is a comfort in this house. If "Warwick" decides on making either of these large hives, and wants more information, I should be pleased to give him correct measurements of both hives and frames.—GEORGE HOWDENSHERE.

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Chrysanthemum Leaves Diseased (W. S.).—No. 1 leaves are infested by the Chrysanthemum leaf-rust fungus (*Uredo chrysanthemi*), which first appeared last year in this country, and was figured and described in the *Journal of Horticulture* the 21st of last October. The only means of riddance is to destroy the worst infested leaves by burning them; but yours are not so far advanced in attack as to render this necessary, therefore we should dust the plants very lightly on the under side of the leaves with a fungicide containing sulphate of copper, such as anti-blight, fostite, or others, using a bellows apparatus; or, if you prefer a liquid application, use sulphide of potassium, half an ounce to a gallon of water, dipping small plants or cuttings in the solution, otherwise spraying or syringing it on, the plants being laid on their sides, so as to wet the under side of the leaves. No. 2 leaves contain the irregular and shallow pustules of the parasite in its earliest form, but the spores are shed and many of the æcidia have not matured, the mycelium traversing the inter-cellular spaces of the leaves and destroying the tissues. This completes the life history of the fungus—first the æcidia form (*Æcidium chrysanthi*), then the uredo, or rust stage (*Uredo chrysanthemi*), and finally the resting form (*Puccinia chrysanthemæ*), all on the same host plant, or different members (in your case) of the varietal forms. Treat as above advised.

Propagating Aralias (Aralia).—You will find the information you require on page 71 of our issue of January 20th of the present year, or just three weeks ago.

Plans of Flower Beds (W. G.).—As you require beds similar to those in Hyde Park you cannot do better than choose such as you prefer as are figured in the book entitled the "Parks and Gardens of London." It can be obtained through a bookseller, or by post from the publisher, 12, Mitre Court Chambers, Fleet Street, in return for 2s. 11d.

Chrysanthemum Mrs. W. H. Lees (G. S.).—Mr. Molyneux writes: "To my knowledge this is the first time a sport has appeared on this Chrysanthemum. There need be no surprise at this, as any variety is liable to sport at an unexpected period. As yet the origin of sports is a mystery. By all means retain the sport, as being yellow it should be a valuable variety coming from such a good stock as that named, which, when in good condition, is one of the best of the Japanese section."

Improving Mossy Lawn (A. K.).—As the soil is of a stiff clayey character, perhaps it needs draining. If the lawn is small, and you can provide a mixture of three parts fresh loam and one part each of lime and wood ashes, to spread on a quarter of an inch thick, after well combing out the moss with a sharp-toothed iron rake, improvement would be certain to follow. The simple mixture used by Dr. Hogg was not for destroying moss, but for keeping the lawn in good condition, and in the field improving the herbage for stock. In the case mentioned on page 75, January 27th, of the moss being "burnt up," and a lawn of grass following, superphosphate was used at the rate of about 13 cwt. per acre.

Lime Water for Destroying Moss on Fruit Trees (Y.).—We have not found lime water thoroughly effective for destroying lichen and moss on fruit trees, but it acts fairly well when continued from year to year, yet not nearly as satisfactory as limewash, this having also a good effect on the land, as it scales off with the dead overgrowths, and thus profits the trees ultimately. A wash of sulphate of copper, 1 lb. to 25 gallons of water, with the same amount of freshly burned best chalk lime, slaked and formed into a wash before adding to the sulphate of copper solution, answers for destroying lichenous growths and preventive of fungoid attacks, applying whilst the buds are quite dormant in very early spring with a spraying apparatus. A very successful fruit grower has found the cost of 10s. 6d. per acre in using the caustic mixture you name a profitable investment.

Fungus under the Bark of Dead Trees (J. C.).—The specimen is the densely felted mycelial hyphae of the bark fungus (*Stereum acerinum*), which may commonly be found on the living bark of *Acer campestre* or field Maple in hedgerows, slowly but surely killing the affected plants. Probably the fungus does not or cannot attack quite healthy trees, but this is mere conjecture, as the trees are not noticed to be unhealthy until the parasite has got a good hold upon them and remedy is out of the question. We can suggest nothing but to clear away the infested trees, stubbing them, thus removing the cause of infestation. Whatever may be necessary to promote health in the trees, such as drainage, must be left to those cognisant of all the circumstances, but we found clearance of affected trees the only safeguard in a belt of Sycamore in a smoky district, this being regarded as the inducement to attack—namely, the impaired vitality of the trees.

Nectarines Losing Their Branches (K. J. J.).—The cause of the Nectarine trees losing the branches on one side one year, and dying on the other side the other year, is gumming. This is due to the growth of a fungus (*Coryneum Beijerinckii*) which destroys the inner bark, and encircling the branch cuts off the supply of sap, the part above suddenly collapsing. The excessive vigour of the new growths is abnormal, and the provocative cause is the pushing of the mycelial threads into the cellular spaces of the young wood, which is followed in due course by a ferment and exudation from the gummy growth, and the branch sooner or later dies. The only known remedy is to cut away all the gummed parts a few inches below where the exudation occurs, and train in young growths. As the spores of the fungus cannot penetrate short-jointed growth with thick elastic epidermal tissues, it is found that lifting those trees which make strong growth induces shorter-jointed and better solidified wood, capable of resisting the fungus and producing better crops of fruit. This we advise: Lift the trees carefully, cut away the diseased parts, if not all at once, as soon as others and healthier are produced to supplant them.

Worms in Tomato Roots (T. P. R.).—The "small worms" are myriapods—the familiar snake millipede (*Julus pulchellus*), which feeds for the most part upon dead or injured vegetable or animal substances. It, however, attacks the living fleshy roots of many plants, and even the crown growths, causing their decay or destruction. The "dry as dust" Tomato roots have been infested by root-knot eelworm (*Heterodera radicleola*), this pest being the cause of the warts on the roots and of the collapse of the plants. We should clear all such away, and burn every particle of root that can be got hold of, then seal the whole soil and walls of the bed with boiling water, thoroughly wetting every part in the completest manner, and if you take out the soil also seal the walls again, and the bottom of the bed. This will settle the eel worms which it reaches with or without phenyle (see Mr. Iggulden's article, page 76, January 27th), and the only further precaution will be not to reintroduce the eelworm with the soil or compost. If this be scalded before use there will be little danger of the enemy reappearing. For the millipedes use baits of Carrots, Parsnips, Mangolds, or Potatoes, preferably partly decayed, and when the animals are near the surface they can easily be scalded where there are no roots to injure, or the pests can be otherwise killed by crushing them with a knife.

Peach Buds Dropping (J. W.).—The shoots have some perfect and a number of defective buds, whilst many have fallen. All the defective buds have a dead central axis, there never having been any or very imperfect formation of the reproductive organs, and this simply accounts for the buds dropping. The roots are in most parts fairly healthy; but there is a minute fungus on some of the fibres, and evidently destructive to the bark, as this is dead as far as the threads or mycelium extends and quite sound elsewhere. The soil is of a very substantial character, and ought to grow Peaches well. The position certainly cannot be regarded as a good one, and the proximity of gasworks will not mend matters: but these obstacles cannot make the difference between an imperfect and a perfect blossom bud, for what suffices for one should for the other if sufficiently adequate for both. We have found lifting and firming the soil the best preventive, yet not always successful, or only for a time, then a dressing of the following mixture had a good effect:—Bone superphosphate, dry and crumbling, five parts; muriate of potash, three parts; sulphate of magnesia, one part; and sulphate of iron, half part, mixed, using 4 ozs. per square yard when the buds commenced swelling, and pointing or scratching in very lightly, afterwards using superphosphate only, a good handful (4 ozs.) per square yard at intervals of six weeks from the first leaves appearing till the fruit approached the ripening stage. Thus the trees had half a pound of the dissolved bone per square yard in addition to that given in the mixture, and with the lifting and otherwise careful treatment became healthy and fruitful.

Zygopetalum Mackayi (Novice).—Two systems, both of which have proved successful, are here given. They do not require frequent potting, and a slight rest after the completion of the growth is beneficial, reducing the supply of water; but never attempt to dry them, as is practised with some plants. One cultivator says, "Although Brazilian it makes grand growth in a cool airy house during summer. The largest growths we ever saw were made in a cool, moist, airy, and partially shaded Odontoglossum house. Everyone admired them, but they did not flower. The Mexican house temperature was next tried: 90° on hot days, no shade, no fire heat at night, when the temperature fell to 45° or 50° very often. So grown the pseudo-bulbs were smaller, the leaves shorter, and almost yellow rather than green, but the growths were sturdy and vigorous. Some gave two spikes, each spike bearing seven to nine flowers. A compost of fibrous peat, sphagnum, and broken crocks is most suitable, and abundance of water when growing should be the rule." Another cultivator remarks as follows:—"Ours are grown among Cattleyas, but it succeeds if managed like an ordinary cool stove plant. It is not particular as to compost, as we have it growing in peat, loam, and a mixture of both. Breaks on plants in all three kinds of compost or soils are producing a couple of spikes each. It is a free rooting plant, and requires plenty of root space. A strong plant with one or two breaks should have a 9 or 10-inch pot. When the pots are too small for the plants one spike from each break is the rule, and very seldom more than one break is produced from a lead, while under liberal treatment more spikes and breaks are common."

Names of Fruits. — Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (T. B., Leeds).—1, Probably a local seedling, worthless; 2, Dumelow's Seedling, also known as Wellington and Normanton Wonder, a good specimen; 3, Hoary Morning; 4, Leathercoat; 5, Winter Hawthornden; 6, resembles a Sturmer Pippin that has been gathered too soon. (P. R.).—1, Easter Beurré; 2, Bergamot Esperen. (S. P. F.).—1, Wellington; 2, Cox's Orange Pippin; 3, Braddick's Nonpareil.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (M. M. P.).—1, *Oncidium tigrinum*; 2, a form of *Cattleya Trianae*; 3, a *Cypripedium* insigne of no special merit. (A. R. F.).—1, *Tillandsia Lindenii*; 2, *Phanix dactylifera*; 3, a Fern, dead. (A. A. B.).—1, *Adiantum pubescens*; 2, *Selaginella Kraussiana*; 3, a variety of *Odontoglossum crispum*. (T. B.).—*Iris tuberosa*, the Snake's Head Iris.

OUR PASTURE LANDS.

WE talk of the vivid green of our spring fields, and rightly so, but this year spring has come upon us so early, or, more properly speaking, we have had no real winter, that the fields are brilliant in colour, and, at the same time, well covered with herbage. So much so indeed, that it is a great temptation to give the order, "Turn out all the beasts for a few hours." No doubt they would enjoy the run, and the cool, pleasant mouthfuls of grass would be as refreshing to them as a crisp salad is to us on a dog day, or the first green Gooseberry tart in warm May sunshine.

Pleasant and beneficial as the outing might be to the stock, it would by no means be so beneficial to the pastures. Nature must have a resting time, and any herbage eaten now is sheer robbery. Frost must come sooner or later, and the coarser, tougher grasses act as protectors for the finer growths, and the patient man finds it pays him better in the long run to wait a bit before stocking his winter grass. Besides, too, the very verdure that pleases the eye betokens a certain amount of moisture in the turf, and much treading by stock is anything but desirable. Four hoofs make a considerable impression when multiplied by twelve or fourteen, and hoof marks destroy as much embryo grass as the industrious mouth.

Pasture land is often supposed to manure itself. All the manurial energies of the farmer are directed to his arable land. Of course this is perfectly justifiable; but if folks would only stop to consider a bit sometimes, they would come to the conclusion that even grass land, enriched with cattle droppings, might be benefited by a little attention. This attention need not always take the form of expensive manures—oh, no! We are not advocates of always draining the pocket. We do plead guilty to stealing a little time—a little horse power. We have often been struck with the fact that so few farmers think it necessary to spread the cattle droppings in the fields. We all know how coarsely the crop grows in any field where the manure heap has stood. If a corn crop, the straw is generally overgrown and rotten, having been laid some weeks before harvest; if a Potato crop, well, those particular tubers are by no means a good sample of the field. And it is just the same with the grass. It is almost smothered by the concentrated mass of manure, and then after recovery, which is a long process, the herbage is coarse and rough.

It may seem a fad, but a boy with a spade or hoe at 1s. a day could effect a great improvement and benefit. At any rate it would bring about uniformity. A party of industrious hungry fowls will do the work equally well, and ask no 1s. per day. The same remark would apply to molehills, unsightly in themselves, but so valuable as top-dressing. There is another form of cheap top-dressing obtainable in many places for leading, we refer to roadside scrapings. In these days of such activity on the part of road surveyors much good work is done on narrow roads by the ploughing out of about two or three farrows each side of the road. This material must be carted somewhere, and it forms an excellent and cheap dressing.

On most farms, too, are to be found banks formed of the deposit removed at great labour from the dykes. It is never carted away in the wet state for obvious reasons, but when thoroughly dry is well worth carting away to the nearest grass land. We were amused lately in reading remarks by a parson on the excellence of grass land adjoining the homestead that is always good. It is a case of first come first served, and the far-off pastures are often left to that more convenient season that never comes. In the corners of many fields will be found heaps of decayed vegetable matter, such as Potato tops, the residuum of the Twitch and Thorn burnings, all so good if only spread about.

We do not consider horses enrich a pasture much; their manure is among the least valuable, and therefore the horse pasture should receive a little extra attention. None of these little "tonics," if we may so term them, entail a heavy bill; they are all, as it were, home productions. Now we shall speak of a few resortatives that must be paid for in current coin.

One of the signs of the change of thought that comes with passing years we find in the fact that never, or hardly ever, are bones used as dressing for grass. Our fathers swore by them (we mean $\frac{1}{2}$ -inch bones, not the cooked varieties), and considered they were the one great need of grass land. *Nous avons changé tout cela.* Basic slag is the universal remedy recommended now, a substance which did not exist in our fathers' time and not till lately in our own. It has the merit of being cheap, and for some classes of grass land is most valuable, containing as it does a percentage of something like 17 of soluble phosphate. Unlike superphosphate, the benefits of basic slag are not so quickly exhausted, and on coarse rough grass the result is excellent. The quantity applied should be about 5 cwt. per acre.

For poor mossy grass (the moss denoting a deficiency of lime) we recommend a good liming. Lime destroys the moss and renders sour land sweet. Where lime has been applied a good plant of White Clover will generally make its appearance. For thin grass, liable to dry out in a hot season, a dressing of common salt will be found of value as tending to retain the moisture. Of course there are districts where lime is not very easily obtained; in cases of that sort we should advise the application of basic slag, as besides the valuable phosphoric qualities it also contains much lime. We are fully aware that we shall find many who will not agree with our remarks on the subject of giving our pasture lands a winter rest. Necessity, we know, is a stern mother, and many farmers are almost compelled to keep their stock out of doors during winter; but two wrongs never yet made a right, and the only case where we would tolerate winter grazing is the grazing of rough park land by hardy Welsh or Scottish cattle. The rough park can never be made really good grass, and the little Welsh and Scottish cattle will live and do well where a better class of stock only deteriorate.

WORK ON THE HOME FARM.

Where are we? Can it be true that we have not yet left behind us the winter quarter? The evidence of the morning paper is in the affirmative, but our lawn is showing symptoms of the urgent need of a mowing machine, and we really do not know where we are.

On the whole, and looking back to the lessons which experience has taught us, we suppose the calendar is the surest guide, and that we had better defer our sowings until the Ides of March, and direct our attention to spring cleaning. Now, in the household this is an operation that always involves an immense amount of dust, an article with which we do not make much acquaintance out of doors until March, but having the dust let us hie us to the cleaning.

Spring cultivators are making splendid work, and seem to be a greater boon than tying-reapers—at any rate, they have become universal in a much shorter time. Old-fashioned drags and cultivators are now almost unsaleable, and it is not surprising, for the new cultivators are useful for so many purposes, and for dragging out twitch they are unapproachable, the lifting action having such a wonderful effect in leaving everything light on or near the surface; a set of light harrows and a chain harrow to follow then soon complete the operation so well begun, and as much is done towards cleaning the land at one operation as under the old conditions often required three dressings to satisfactorily perform.

We have rolled our Wheat, but not harrowed it as yet; we have the kainit in the shed, and shall sow immediately, and then harrow the Wheat at the first dry opportunity. Larks did their worst, but the late-sown Wheat, thanks to the mild weather, pulled through, and now looks well. Woodpigeons are now the pest, and they are eating off the young Clover as fast as it grows. A raid has been organised, and every Wednesday afternoon for a month every plantation in the county will contain a loaded gun in the hands of a farmer sworn to exterminate as many wild pigeons as possible. Last year 1500 were killed, not a large number for a county, but much good resulted.

REMARKS.

- 30th.—Mild, with high wind and a gale at night; slight showers early and between 11 A.M. and noon.
 31st.—Almost cloudless till 11 A.M., and brilliant throughout.
 1st.—Rain from 2 to 3 A.M.; fair early, bright sun from 9.30 to 10.30 A.M., then cloudy, and faint sun in afternoon.
 2nd.—Bright sun almost all morning, with high wind, but occasionally cloudy.
 3rd.—Mild, with alternate sun and cloud in morning; frequent drizzle in afternoon and rain at times; lunar halo in evening.
 4th.—Almost continuous light rain mixed with wet snow till noon; frequent sun in afternoon; clear night.
 5th.—Almost cloudless morning; sunny afternoon; fine night.
 Temperature still very high, but barometer lower and rather more rain —
 G. J. SYMONS.

communications must be addressed to 8, Rose
Hill Rd., Wandsworth, S.W.

THE ROYAL HORTICULTURAL
SOCIETY: MEDAL AND OTHER AWARDS.

THOUGH prominence is given to the following
communication, it is not to be implied that
we are in full accord with all the propositions of
our correspondent, but rather because the whole
subject of making awards at the Drill Hall
meetings appears to merit greater consideration than
it seems to have received.

All members of these bodies have reason to be
grateful that the Council is presided over by a
gentleman of Sir Trevor Lawrence's good sense
and discretion. His graceful remarks, the moment
appealed to, of an arrangement with respect to
making awards at the Drill Hall meetings, so likely
to fail, showed at the recent annual meeting that he,
at least, fully recognises the services which the mem-
bers of these Committees render to the Society. It
was rather curious that the Fruit Committee should
have been the only one that in a body at the recent
Drill Hall meeting objected to the Council's order,
and this in the interests of the Society. However,
the President was evidently in favour of the sug-
gestion that each Committee should do as the
Floral Committee has done for several years—
appoint a sub-Committee to make the medal
awards to such exhibits as are entered to that
Committee.

But, after all, as the object of the Council is to
reduce the number of medal awards, will the
proposed sub-Committees be productive of the
Council's desired end? Judging by the Floral
Committee's experience I should say not. Did not
the mixed or hybrid Committee of the 8th inst.
make just as many awards as would the Committee
under ordinary conditions have done? Was that
the reason why these awards were kept from the
Press? or do the Council think, as I think, that
the publication of these medal awards in the papers
rather intensifies the craving which seems to exist
for them? I am not sure whether, except at the
great shows such as the Temple and Crystal
Palace, it would not be a good thing to publish
only the medal awards to gardeners or amateurs.

They have nothing to gain beyond the awards, and hence merit encouragement. But, at the same time, I say emphatically that every Fellow of the Society who visits the Drill Hall, ought to be most thankful to members of the horticultural trade for their splendid liberality in making the meetings so interesting and instructive.

Now I suggest that no medal awards whatever be made to trade exhibits at any Drill Hall meeting; but seeing that many members of the trade exhibit repeatedly, that at each meeting the sub-Committees making awards be authorised to give to each trade exhibitor so many marks or points apportioned to the merits of the respective exhibits, and that at the end of the year the Council award to the trader having the highest number a gold medal, providing also silver-gilt, or silver medals, in value relative to the number of points obtained for the year. No trader should be awarded the gold medal more often than once in five years, as that would give others a chance to win it also. With severe limitations placed at each meeting upon the space allotted to each trader, and upon the number of marks granted in each case, I submit that the result would be to secure in really competitive form a remarkable series of trade exhibits all through the year, which would serve to maintain the meetings in a high state of excellence. I can conceive of no other satisfactory way of reducing the number of medal awards; and as to abolishing them absolutely, I think that is an insane idea. With respect to certificate of merit awards, I still hold that no better or more practical proposal in the direction of reducing these has been yet made than mine, that none should be granted except by a majority of two-thirds of the members present.—A. D.

[We are not in the least surprised that the Council should view with some apprehension the generosity of the Committees in awarding medals and other high honours at the Drill Hall meetings. Last year it would seem that more than 400 medals were granted—namely, by the Floral Committee 264, the Orchid Committee 83, and the Fruit Committee 64. Did some of the members of the Council think that by a mixed medal committee of plantmen and fruitmen one would act as a check on the other? If so, why stipulate for twice the number of floral over the fruit experts, whereas these latter recommended the smallest number of medals? Moreover, the members of the Fruit Committee showed in the most practical way possible their willingness to meet the reasonable desire of the Council by supporting a proposal that high honours shall only be granted by a two-thirds majority vote. This certainly would have led to a diminution.

The proposal was not accepted, but in lieu of it an instruction was issued for the formation of a committee of nine, one-third of this number from the Fruit, two-thirds from the Orchid and Floral Committees, the nine members to go jostling against each other through all the departments for recommending medals, some of them knowing very little about Orchids, others little about fruit, and perhaps half of them not being up-to-date with florists' and other flowers and plants, yet all the votes having equal weight!

The scheme could never have been fully considered by the Council. It involves a breach of the principle that has been peculiar to the Royal Horticultural Society since the Committees were established—namely, that the honours awarded are determined by experts in each section, and it is this which has invested them with a weight far exceeding that of any honours which may bear the same name granted by any other society in the kingdom, and, perhaps, out of it. The principle in question is a cardinal and distinguishing feature of the R.H.S., which it is hoped will be maintained in its integrity. There can be no sounder line of action than that each Committee shall be responsible for its own decisions in its own special department, and a mixing of the three would in the very nature of the case be a weakening of all.

As to the examination of exhibits not placed on the Committee tables, but arranged in the body of the hall for display, it has been the custom for all the members of the Fruit Committee present to go round the hall in a sort of crush and scramble for examining the collections. Thoughtful inspection, careful comparison, and quiet

discussion on the merits and demerits of the produce is practically impossible under such conditions. Far better would it be to delegate three members from the Committee who rarely if ever exhibit, such as Messrs. Bates, Barron, Smith and others who have also had much experience in judging; let them have ample time for examination (just as in the case of judging the dessert fruit for the Veitch prizes), and the work would be well done. All persons who have had much experience in adjudication at shows know quite well that the greater the number of judges above three the greater the liability to confusion and mistakes. The plan of having an assemblage of all the judges at provincial shows to determine the prizes in certain important classes has been tried, found wanting, and almost, if not quite, in every case discontinued.

The principle suggested by "A. D." for the determining of medals is exactly that which is adopted by the National Amateur Gardeners Society and many other associations which hold periodical meetings, and it answers admirably, the cumulated marks determining the prizes at the end of the season. It is followed also at great provincial shows where medals are provided for meritorious non-competitive exhibits, only in these cases the prizes are determined at once, according to the number of marks the judges have recorded for the various exhibits. In no other way could the work be done so well. A very high number of marks indeed carries a gold medal; a reduced, though still high number, a silver-gilt; lesser, yet meritorious marks, silver medals, and so on. Awards which are based on carefully considered lines, and represented in figures, invariably give the greatest amount of satisfaction to all concerned—show authorities and exhibitors.]

RED SPIDER IN VINERIES.

It may be affirmed that in the whole routine of Grape growing, in certain localities at least, more worry, trouble, and injury arise from the inroads of red spider than from any other single source that can be named. Many have been the preventives and remedies which have been recommended and tried to combat the evil. In many cases the "cures have proved worse than the disease," at least they have not only been ineffectual but nearly as injurious as the pertinacious little pest. No wonder that a friend on being once asked how his Vines were doing, exclaimed that he was "sair hadden doon we reed speeder!"

It is the practice of many persons in order to prevent and combat the pest to regularly syringe the Vines with as clear water as can be had up to the time the Grapes begin colouring. The objection against this is that in numbers of cases the water leaves some deposit behind it, so that if it do accomplish the end in view it disfigures the berries, and no gardener or his employer likes that; nor does it always effectually accomplish the end in view—it simply displaces without killing the enemy, which seems cunning enough to get on to the upper surface of the leaves, and there it may laugh at the syringing.

Another, to me, objectionable evil attending syringing is that it drives the leaves out of their natural attitude, and the weight of water causes their footstalks to bend. Then unless the houses are carefully ventilated there is a danger of chilling the leaves—generally termed scalding—by rapid evaporation of moisture from their surfaces in a bright morning. Sprinkling surfaces with sulphate of ammonia is sometimes resorted to, but it is a ticklish process, and is seldom satisfactory. Various other remedies have been applied, such as sulphur mixed with hot lime, or painting the pipes with a mixture of sulphur and lime or soot of the consistency of paint. I cannot say that I ever saw any of them prove completely effectual, and for many years have not resorted to any of these appliances.

What I have found completely effectual, after having found out that there are two sorts of sulphur in commerce, is the application of one of these to the hot-water pipes, and applying extra fire heat for eight or ten nights consecutively. I do not think it is generally known by gardeners that there are these two sorts of sulphur. The one is flaky, something like fine powdery snow; the other like ashes, though much finer. The latter is the effectual kind, and is known as Sicilian or sublimated sulphur, which is used by manufacturers of tweeds and other woollen fabrics, and which drysalts generally supply. This was not applied in the usual way. The pipes were moistened, and so much dry sulphur put on them as could be got to rest on their upper part. Extra fire heat was then afforded as mentioned already, till on entering the vineries at night strong fumes of sulphur were felt. When the heat was rushed up to the desired amount it was then moderated, and in the morning either checked as much as possible, or the fire drawn off as circumstances called for.

The precaution necessary is never to begin this sulphuring till the Grapes are larger than the largest peas or nearing the stoning period, and are free from all danger of what is termed rusting. I never observed the least ill effect on the Vines from this treatment, provided it was not applied too early. Unless, indeed, that from over-moisture and improper ventilation, the under leaves of a Vine became warty. The warts became black. By the use of a pocket lens it is easily seen when all the insects are dead, and their eggs become black and vanish. Then the extra fire may be stopped, but the sulphur left intact. I have never once found this remedy fail in clearing Vines of red spider, and for many years I have seldom or ever syringed a Vine from the time they were fairly started till the fruit was all used; and I have had Hamburgs and other Vines keep their leaves intact without a blemish till they dropped off the pale yellow colour of Horse Chestnut leaves when ripe and falling from the trees.—DAVID THOMSON.

FAIR DEVON.

(Continued from page 83.)

It is remarkable how the principal species are found in colonies along these stone fences, and I have observed in some places from 50 to 100 yards of surface nearly covered with one sort, then another long or small space occupied with a different kind, and so on with perhaps half a dozen distinct forms in succession. Very rarely are they found mixed, and even species of the same genus appear antagonistic to each other, or at least do not associate. Amongst these colonies of one kind searchers may find some abnormal varieties, the crested and much-divided fronds of which render many of the forms of wild Ferns so extremely beautiful. But the explorer requires a keen eye and considerable patience to discover such departures from the types, and thousands of plants may be examined without observing the slightest tendency to anything unusual. Some peculiarity of conditions seems necessary to set up a variation, and even then it is rarely perpetuated in a state of Nature.

One of the most distinct, though it is not the most abundant of the Ferns that came under my notice, is *Asplenium Adiantum nigrum*, the Black Spleenwort, of which such large quantities of fronds are seen in Covent Garden Market as the "French Fern." It is a handsome Fern, the bright green shining fronds contrasting with deep purple or black stems, and it is one of the few which can be grown in both sunny and shaded situations. I observed some marked differences in the size of individual plants, accordingly as they were growing high up on the "fences" or near the base, and the dimensions differed, too, on opposite sides of the same road, the stronger plants being in the lower situations and shadier spots. Beyond this difference in mere size scarcely any variation was noted, though one closely allied to the finest of the abnormal forms, the beautifully crested *grandiceps*, has been found in Devonshire, the original variety being a native of Ireland. Another very peculiar and interesting variety of this Fern, *caudifolius*, which has the tips of the fronds and pinnæ terminating in long, curiously attenuated portions like tails, has also been found on Dartmoor. The Black Spleenwort is one of the easiest of our native Ferns to grow, and is admirably adapted for a rockery, where a light soil and well-drained, but not dry position, can be allotted to it.

The common Spleenwort, *Asplenium Trichomanes*, is largely represented on the "stone fences" of the Devonshire roads and lanes, and in one place particularly, in the neighbourhood of Tavistock, I remarked a length of wall of over 80 yards covered with this elegant little Fern, as even and regular as if they had been cast in a mould. The fronds, with their dark stems and small rounded pinnæ, radiating equally from the centre, have a unique appearance, like rosettes dotted over the surface and peering out of every crevice. It is one of the most constant of British Ferns, and very few variations have been found, chiefly of the crested type, with the tips of the fronds deeply divided; but it is a doubtful addition to the attractions of the species in this case. I have had plants of this Fern in pots in a cool house for years great and abundant, small pieces of stone suiting it well.

Blechnum spicant, the Hard Fern, occurs in colonies on the walls like the others, but is found in other situations as well, where the soil is moist, not too heavy, and free from lime. It grows freely and strongly, and the contrast between the tall fertile fronds with narrow pinnæ, and the shorter, broader, and more lasting sterile fronds, is very notable. For culture in pots or on rockeries it is one of the best. Variations are more plentiful amongst plants of this Fern than of the two preceding, and several have had their origin in Devonshire, or are found there as well as in a few other districts. One of the most distinct is *polydactylum*, which occurs in North Devon, and has the fronds divided into several portions at the tips. *Congestum* is a small compact variety found on Dartmoor, and *concinnum* is another neat

little Fern from Exmoor. Of other variations the crested forms—*cristatum* and *ramo-cristatum*—are graceful, and a "sporeling" from one of these named *glomeratum*, which forms a dense crested mass of growths in a compact globular form, is one of the most peculiar of all the British varieties.

Polypodium vulgare is abundant on the walls or "fences," but generally on rather higher and drier situations than the others, its slender creeping rhizome requiring little soil. Its even pinnate fronds vary but little in size and still less in shape as regards the majority of colonies, but the Cornish Polypody, *P. vulgare cornubiense*, must take its place amongst the most beautiful of the abnormal varieties of British Ferns; it has indeed been appropriately named *elegantissimum*. The fronds are very finely divided into small segments, until the original pinnate character is quite lost, and it could scarcely be recognised as a Polypody. It is a charming little Fern, and should be grown by all who admire graceful foliar form.

The Hart's-tongue, *Scolopendrium vulgare*, affords a wonderful study in variation, and there are Fern lovers in the neighbourhood of Sheffield and Manchester who have formed astonishing collections of this Fern. In the Devonshire roads and byeways it is very abundant in the lower positions where there is a greater abundance of light moist soil. Even in its simple forms the undivided straight shining green fronds are both distinct and attractive, but amongst the "crispum" forms, which have the frond margins undulated until they resemble green frills, some exquisite varieties have been either raised or found. Other types range from those with slightly crested or cut fronds to some so densely and closely cut up that they become almost moss-like, and bearing no resemblance to the original forms. *Conglomeratum* is one of the most marked of these, and is well adapted for pot culture. The Hart's-tongue is an excellent Fern for the base of rockeries or amongst old tree roots or stumps, and is always admired. Devonshire is so remarkably the home of Ferns that some excuse will be found for devoting this letter to a few of the most notable, but only the fringe of a great subject has been touched, a long holiday could be delightfully spent in searching for these natural gems.—VIATOR.

(To be continued.)

VEGETABLES FOR HOME AND EXHIBITION.

BROCCOLI AND CAULIFLOWER.

THOUGH these vegetables may be classed as near relatives, the former is the hardier in constitution, and the latter has the advantage in appearance and delicacy. Both in their season have an equal claim to popularity, and during recent years many acquisitions in the shape of new varieties have been introduced. These have had the effect of lengthening the season during which good Cauliflower and Broccoli may be produced, this end being reached by successional sowings and plantings. Like all other members of the family both are gross feeders, and a fairly strong soil, fed with good farmyard manure, and afterwards stimulated with a little chemical, are the conditions under which they thrive admirably. Plants that have to stand the winter must be strong and sturdy, and it is generally the ill-fed specimens that are the first to succumb. In generalities the culture of the two are similar, but in particulars they vary.

The first sowing is to provide heads for cutting in the autumn, and should be made in March and April, the former in a frame and the latter in the open ground. Robust growth is necessary from the first, therefore the seedlings must be thinned early and planted before they become crowded. If ground is not vacant at this period the seedlings should be pricked out and afterwards transplanted. The land ought to be enriched with good manure prior to planting, and the Broccoli dispersed at about 2 feet apart each way. If the planting can be done in showery weather so much the better, but if not applications of water must be supplied to give them a start. The best varieties for providing an autumn supply are Veitch's Self-protecting and Walcheren. Good Broccoli at this period is very acceptable, and it may be obtained by following the above methods.

Towards the end of April another sowing should be made, this time for winter Broccoli. Snow's Winter White, Vanguard, with a second sowing of Self-protecting, are good varieties for the winter supply; and as seasons, climate, and soils vary it is a good plan to commence planting early, and continue till sufficient have been put out. A third sowing should follow in May for providing heads the following spring and summer, and by this means a succession of the family is practically kept up through the year, as the latest of the Broccoli is closely followed by early Cauliflower. Leamington, Model, and Late Queen are good for the latest sowing, the latter being an excellent variety, frequently producing heads in June.

Numerous methods are adopted for the winter protection of Broccoli, though in mild seasons, such as the present one, it is not

necessary, and the finest crops are obtained from undisturbed plants. It is always well, however, to be prepared for emergencies, and one of the ways of protection is to heel in the plants on the approach of severe weather, with heads to the north, disturbing the roots as little as possible. By commencing at the north end of a row, and following the plants in succession, they assist to protect each other, and the work is completed without disturbing the roots to any great extent. Some growers adopt other methods, such as taking up the plants and storing them in sheds and cold frames.

The principles of culture applied to Broccoli are also suitable for Cauliflower, though being of a tenderer nature greater care is required in protection. In order to maintain a succession two, and in some cases three, sowings are necessary. The first should be made in February, and the seedlings from this one require some attention to prepare them for transplanting. Sow the seeds in boxes over gentle bottom heat, and when the plants begin to crowd each other they should be pricked into a frame in a bed prepared of old potting soil with a little spent Mushroom bed refuse added. The idea is to grow the plants sturdy, yet without a cheek, as this frequently causes "buttoning." By adding the manure from a spent Mushroom bed to the soil the plants lift with good balls, and when thoroughly hardened and large enough they should be finally planted on well prepared and manured ground. Water applied during dry weather will assist the plants considerably, as also does an occasional surface dressing of a chemical fertiliser. Good varieties for early sowing are Extra Early Forcing, Snowball, and Early London.

The second sowing should take place about the middle of April, this time in a sheltered bed outdoors. No overcrowding must be allowed, and the plants ought to be pricked out once before being finally transplanted. Ground as it becomes vacant from early summer crops is suitable for autumn Cauliflowers, of which Autumn Giant has no superior. Eclipse and Waleheren are also excellent varieties suitable for table or exhibition. Some growers make a third sowing in September, but with an adequate supply of Broccoli coming on this is not really necessary, as by sowing an early variety in January or February there is very little time lost. Autumn-sown plants will keep well through such a season as the present, but in a severe winter the matter is more difficult. The plants are often potted and stood in frames or cool vineries, and planted in their permanent quarters in the spring. There are certainly some advantages gained if good autumn-raised plants can be safely kept through the winter, as under favourable conditions the heads turn in early, to be followed in succession by the spring-sown plants.

The Cauliflower is a favoured vegetable on the exhibition board, and when in season no large collection could be considered complete without them. The season of a Cauliflower's perfection is short, as a good specimen to-day, especially in the summer, is over to-morrow. Would-be exhibitors should always cut the close heads early in the morning before the dew has evaporated from them, when they will be fresh and white. A moderate-sized, firm, white and crisp head is the best for the purpose, and as they are invariably shown in pairs, these should be as even in character as possible. Outer leaves are better removed, but beyond this too much trimming is not recommended. Quick unchecked growth is the secret of success with this plant, buttoning and other failings being the result of stoppage or wrong treatment. Surface culture of the soil is an important point that should never be overlooked, and during dry weather applications of liquid manure are of valuable assistance in stimulating growth and building up the plants. Always remember that it is the best-grown plants that produce the choicest heads, and these are obtained through no newly-found theory, but by doing everything thoroughly and at the proper time with the indispensable aid of the kindly conditions of Dame Nature.—GROWER AND JUDGE.

DIGGING AND TRENCHING.

SPRING *versus* WINTER.

YOUR correspondent, Mr. W. Pea, "confounds things that differ." If he will look at my remarks in the Journal of January 20th he will read, "After a long and varied experience my conviction is that the season to be recommended for this work, in order to realise the object named, depends entirely on the nature of the soil and subsoil, as well as on the rainfall of the district." I have no intention of entering any further on a wordy and rhetorical argument or controversy on this subject. I have given instances in which my contention has been proved beyond dispute by others whose experience and success has been well acknowledged, and this experience tallies with the laws that govern material things, which Mr. Pea seems to treat very lightly. I have had to deal with soils where the workmen had to dip their tools in a pail of water to make the next spadeful slip off it. It had been frosted and tumbled about for years to no purpose. It was turned into a tillage that would grow almost everything well, and was easily cropped, but by quite another agency.

Mr. Pea is quite correct when he says that soil holding more water in suspension has a greater shattering power exerted on it when frozen than

has one with less water in it. This is strong proof that my contention is right. The fact that the soil is thus rendered more porous gives it an increased capacity to hold the moisture. Hence you have prepared for yourself an aggravated condition of puddle to deal with, because after the melting of the ice the excess of water remains, and the greater the amount the longer the land of necessity remains unworkable.

Mr. John Roberts, Tanybwllch Gardens, in Wales, in writing in the "Garden" quite recently, under the heading of "Vegetable Growing Under Difficulties," says, "The operations of digging and trenching are left till early spring, and I wish to emphasise this, for so convinced am I of the advantage accruing from the practice where the rainfall is generally heavy, that I have adopted it for many years;" and he goes on to say that such labour in winter, owing to the wet climate, would be worse than useless, whereas he finds if the work be left till spring the ground is more friable and workable. I have before me a letter from Mr. Pettigrew of Cardiff Castle Gardens, in which he remarks, "I have read your paper on 'Digging and Trenching.' I quite agree with what you say. I have experienced it at Dumfries House, and Mr. Murdock, who, for forty years, was my predecessor, had the same experience." This was in a wet climate and on heavy ground. Another correspondent, in a letter received this morning, writes, "I have known scores of working men on strong land who would allow no one to dig it for them in winter if the work were done for nothing."

It rather startles one in these days of technical teaching to be told that "philosophy (in other words the laws of Nature) is one of those cheerful things which do useful fair weather duty, but comes to grief under stress of circumstances." Will Mr. Pea tell us one of these circumstances under which these laws have been proved to be inoperative? He may depend upon it they are "inexorable" in fair weather—and in foul, and let man do his utmost he cannot ignore them with impunity. They will—speaking figuratively—lay him in a trench if he attempts it.—DAVID THOMSON.

THE SHERWOOD £10 10s. SILVER CUP FOR ANNUALS AND BIENNIALS.

N. N. SHERWOOD, Esq., Master of the Worshipful Company of Gardeners, having signified his intention of giving a silver cup annually of the value of £10 10s., and having left to the Council of the Royal Horticultural Society the decision as to what it shall be given for, it has been decided to offer it in 1898 as follows:—

The Sherwood silver cup, value £10 10s., will be given to the exhibitor who shall obtain the highest total number of marks at the meetings in June, July, August, and September 6th of the present year for collections illustrating the suitability of annuals and biennials as cut flowers for decorative purposes.

The attention of intending exhibitors is particularly directed to the Society's "Rules for Judging," sections 160, 161, 169, &c.

Exhibitors may exhibit at any one or more or at all of the meetings during the months named. Marks will be given at each meeting, and the total announced after September 6th.

The contents of each tube (section 169) must consist of one variety only, but in addition to the flowers shown in tubes an exhibitor may set up at each or any of the meetings not more than three plain glass vases containing an assortment of varieties and kinds arranged for effect—all stalks touching the water or sand. The vases must be provided by the exhibitor, and must not exceed 6 inches in diameter, and may be filled with water or with wet sand at exhibitor's pleasure, always remembering that the clearness of both water and glass is a distinct point of advantage in decorative vases.

Notice of intention to compete, and space required, must be sent to the R.H.S. Secretary, 117, Victoria Street, at least the Thursday before each meeting.

The details given on page 48 of the Society's "Arrangements, 1898" (above quoted), do not appear to some people sufficient, and various applicants have asked the following questions, which, with their answers, the President and Council would be greatly obliged by your kindness in publishing for the information of others.

Q. "The contents of each tube must consist of one variety only." Am I to understand that *Coreopsis grandiflora* and *C. Drummondii*, or *Nasturtium Cloth of Gold* and *N. Crimson King*, and so on, may not be exhibited in the same tube? A. They may not.

Q. Are the tubes "not to exceed 3 inches diameter at the top side?" A. They must not exceed.

Q. "The vases must be provided by exhibitors, and must not exceed 6 inches in diameter inside." Does this apply to the "plain glass vases" only? A. Yes. The tubes must not exceed 3 inches nor the vases 6 inches.

Q. Who provides the tubes? A. Exhibitor, unless he is content with the stoneware jars the Society provides at all times.

Q. Will Regulation XI. be enforced? "All specimens must be the bona fide property of and grown by exhibitor." A. Yes.

Q. Must each exhibitor stage—i.e., arrange—his own exhibit, or may he call in professional help? A. A special person may not be procured for this special purpose. The exhibitor or his gardener, or some member of the family of either, must arrange the exhibit.

Q. Can the exhibit be repeated? A. Yes.

Q. Will other foliage be allowed? A. Only the foliage of the variety itself.

Q. May Grasses be mingled with flowers? A. No.

[We hope all is clear now, and some charming exhibits may be expected.]

*LÆLIA ANCEPS OWENIANA.*

THIS handsome form of *Lælia anceps* received an award of merit from the Orchid Committee of the Royal Horticultural Society on December 13th, 1892. At that time we gave an illustration of the flower, and this we reproduce at the request of "D. B. C.," the issue of that date being out of print. It was exhibited by Mr. Owen, Selwood, Rotherham, and was described as follows:—It is a very distinct variety, and attracted much attention. The sepals and petals are of a brilliant rose colour, paler at the base, and with white patches. The lip is a rich magenta, the yellowish throat being streaked with the same colour.

DENDROBIUM SPECIOSUM HILLI.

MAY I be allowed to say a few words in praise of the much-maligned *Dendrobium speciosum Hilli*? I remember, some four years ago, buying a fine specimen plant of this Orchid at Protheroe's Auction Room, when a friend, a well-known Orchid chief, who happened to be standing by, laughingly exclaimed, "Oh, you have bought that brute, have you? I wish you joy. I have grown it for years, but never a prospect of its flowering."

My plant has been now a fortnight in bloom, with some sixty yellowish-white flowers, on three gracefully drooping sprays, each over a foot in length, its lovely, delicate appearance, grouped among Orchids of varied colours, amply repaying me for having to wait so long.

My treatment has been that always recommended, but last autumn I adopted quite a kill or cure system, leaving the pot out under a north wall until the end of November, and giving no water; then I introduced it into the warmest corner of the Cattleya house, and liberally treated it with Beeson's plant food, the pot then being full to bursting with roots. Under this heroic treatment the long dormant terminal buds began to show flower almost directly, with the successful result above mentioned. I thought some of your readers might like to know the success of my treatment of this really beautiful, and especially in the structure of the blossoms, interesting Orchid.—HEREFORDSHIRE INCUMBENT.

DENDROBIUM NOBILE.

THERE is not a more useful Orchid in cultivation than this grand old species, the very worst of forms flowering freely and making a fine show, while some of the better forms are among the most rare and beautiful in collections at the present day. The plant is far too well known to need anything in the way of description. Its culture is easy, and although it is neglected and ill-treated in many places to such an extent that the specimens are ruined in appearance, the fact remains that with ordinary care and a suitable house they may be successfully grown over a large number of years, and rapidly increased in size and numbers.

It will grow well in any moist and warm house, such as a vinery or Peach house in work, a plant stove, or even in Melon and Cucumber houses; while where Orchid houses are at command it thrives well in the compartment devoted to East Indian plants generally. A long season of growth is needed, plants just now starting from the base requiring until July or August before the terminal leaves appear and the pseudobulbs—or stems—swell up. As soon as the top leaf is fully developed the plant should be taken from the heat and moisture and placed in a cooler, rather drier, and very light house, there to be exposed to every ray of sunshine possible, with a view of hardening and consolidating the growth and preparing it for the winter rest.

D. nobile differs from many other of the popular *Dendrobiums*, in that it is not strictly deciduous under cultivation, whatever it is in its natural habitat. But it is certainly different from the evergreen kinds as generally understood, and including such as the *densiflorum*, *thyrsoflorum*, *Farmeri*, and similar types in its habit; and whereas some of these retain their foliage over a very long series of years, that of *D. nobile* always falls in the second year. It likes as long and complete a rest as possible, and for about three months may almost be left alone as far as watering is concerned; but this only applies to well-ripened and hard plants, as green unfinished stems would shrivel badly if much dried.

In late winter the buds appear at the nodes all along the stems, and though they may be placed in warmth with due care, it is not wise to hurry them much, this leading to growth being produced

instead of flower, especially on unripened plants. Just at this period they require careful watching, as slugs, woodlice, and other small insects are fond of eating the young soft buds, and thus a season's work is ruined. The roots should be kept slightly moist, but not overwatered; and care is necessary that the young shoots, which often start at this time of year, are not wetted, as these are likely to damp off, and thus weaken the plants by making them dependent on back breaks.

The best time to repot is as soon as possible after flowering, and not long after this, as a rule, the young shoots commence rooting on their own account, this giving them a good hold on the new compost. The best material to use is equal parts of peat fibre and sphagnum moss, and though many cultivators are apt to recommend bones and manures of various kinds, these are far better left alone by the beginner in their culture. Plenty of rough crocks and charcoal may be added to the material named above; the drainage must be carefully laid and protected, but beyond this nothing else is necessary to produce capital results. I have had as many as forty blooms from a single pseudobulb from young plants grown on from eyes, and this without manure of any kind, either in the compost, or used as a liquid.

The plants may be grown in pots, baskets, pans, or whatever is convenient, the one thing necessary being a well-divided medium that air and water pass rapidly through. After repotting, a little care in watering is well repaid, as the roots are apt to die back in a wet com-

FIG. 21.—*LÆLIA ANCEPS OWENIANA.*

post; but when these have again obtained a good hold of the material, few plants require more water, this being kept up until the bulbs are fully developed. The undermentioned are a few of the best varieties of this favourite plant, and all are first-rate kinds that make a welcome change from the type, and thrive under very similar conditions.

Albinos of well known species are usually rare and expensive, and the white *D. nobile* is no exception to the rule. It is quite a novelty, having appeared in an importation of plants by Messrs. Sander last season. Before flowering it passed into the hands of a well known grower for market, but I believe it was repurchased afterwards by Sander & Co. The flower is of the purest white, with only a faint yellow tinge on the lip, and as only one small plant appeared it is likely to be rare for some time unless it again turns up. It is named *D. n. virginale*, and is quite distinct from such kinds as *D. n. albescens*, *D. n. album*, *D. n. Amesianum* or even the beautiful *D. n. Ballianum*, all of which show in greater or less degree the purple tint on the lip as in the type form.

Quite a different thing is *D. n. Cooksonianum*, which in addition to the purple blotch on the lip has this repeated on the petals. It first appeared at Heathfield House, Gateshead, and thus obtained the name of *Heathfieldianum*, but is now almost universally known as *Cooksonianum*. The deeply tinted *D. n. nobiliss* is a rare and beautiful form, quite distinct from all others, and one of the rarest. Its nearest affinity is *D. n. Sanderianum*, another very deeply coloured and good variety. *D. n. pendulum* is not common. It has pendulous stems, consequently it makes a good basket plant; the flowers are of various tints. *D. n. Wallichianum* is a tall growing fine form, not so good as the rare kinds mentioned, but quite superior to the ordinary type. —H. R. R.

THE ROSARIAN'S YEAR BOOK.

THIS welcome annual has been in the hands of many rosarians for some few weeks, but lovers of Roses generally may well possess it. All who know the Rev. J. H. Pemberton will heartily endorse what the Editor says about him. A more competent judge cannot be found, nor one more closely acquainted with our old-fashioned and garden Roses. We have few—very few—such *bonâ-fide* and energetic amateurs as the Revs. J. H. Pemberton and A. Foster-Melliar, who it is believed personally do all but the digging and hoeing to their Roses. Nor have we more reliable contributors to Rose literature.

When we quote from the Editor's opening chapter that the Rev. J. H. Pemberton "has gained the challenge trophy three times, been placed second six times, and third three times, but never out of it altogether; that he also staged for the Jubilee trophy nine times, gaining it four times, placed second three times, and third once," and that he was the first to re-introduce our single and semi-doubles of long ago, it is self-evident we have here one of our very foremost authorities, amateur or otherwise, and his portrait forms an appropriate frontispiece to the "Year Book."

Miss Grahame's short paper is so true to life that one almost fancies oneself once more busily engaged in the trials and hurry of staging. What a great difference there is in some in this respect! The cool and methodical man gets on and does treble the work accomplished by one who fumes and flurries because every official or assistant is not at his immediate beck and call. He cannot for the life of him call to mind the name of a certain Rose, and yet is perfectly conversant with it. Incessantly changing and re-arranging his flowers, even in a twelve or eighteen, and, after all, goes round when judging is completed only to find, not a first or second prize, but "disqualified for duplicates."

Several of such cases were seen during the season of 1897, and not the least guilty of these are some of our old exhibitors. Many, too, will re-arrange a bloom and not shift the name label at the same time; the consequence is that two blooms are incorrectly named. A box of twenty-four has been observed with no less than eight Roses wrongly named, simply through this hasty re-arranging of four blooms. Several old hands will take their Roses unnamed (except in the case of a few new varieties), select the best twenty-four—or whatever the desired number—when they arrive, and quietly write the names upon the spot.

This is no doubt an immense advantage, for however nearly they may be staged at home there are certain to be many alterations. Besides, to write so many names at home makes it very confusing to find the right one when finishing the staging. The necessary number being written just at the last is a great safeguard against duplicates. The remarks on the provoking watering-can, and the greetings from friend to friend, are delightfully pithy.

There is an exhaustive paper upon "Yellow Roses" from the Rev. A. Foster-Melliar. It is very evident that *Maréchal Niel* behaves better in the open with this amateur champion of Tea Rose growers than with the majority of us. Many persons will agree with him respecting the so-called White *Maréchal Niel* being a misnomer, as has more than once been indicated in your pages.

The great necessity of more careful selection of buds when propagating Roses cannot be passed over, and it is not surprising to find so high an authority alluding to it so strongly. Unless we continue to work from the strong shoots of many of our climbing sports from those of only normal growth, much of the progeny is apt to revert to the normal type. More than one case has been observed where a Rose has greatly deteriorated from this promiscuous selection of buds; so much so that the same variety, one taken from the nursery and the other from an enthusiastic amateur's home-raised stock, could scarcely be recognised as the same. In the first case every available bud was used, whereas, a very few only being wanted in the second, the best were selected.

Quite a heated argument took place last year at one of our large Rose shows in which the writer joined. Some declared a certain Rose was of

no use, and certainly would not find a place in their collection; while another extolled it as being among the very best we had. All were speaking from experience; but the first had purchased from trade growers, who wished to make every piece into a plant as soon as possible; the other had been privileged to receive a plant from the raiser, consequently his was of the best strain—if such a word may be used in this connection—while the others had, unfortunately, got hold of weaklings propagated from weaklings. This is an interesting subject, deserving of more attention than it has generally received. The allusion to the great desirability of more prominent and numerous stamens in the case of single Roses is very apt.

The Editor's exhaustive paper upon "The Rose and the N.R. Society for 1897" brings the whole of the past season and its pleasurable, as well as its few unpleasant incidents closely before one again. All who enjoy the acquaintance of the genial veteran, exhibitor or not, would sadly miss his presence at our shows, while his happy as well as instructive writings for so many years have been welcomed by thousands. The expressive hope for future pleasant meetings at the end of his paper will be echoed by all.

There is an interesting "Chat about Rose Sports," from Mr. A. Piper, in which we once more find that there is nothing new under the sun. The grand new Tea, *Muriel Grahame*, it appears, originated with him upon a *Catherine Mermet*, and a considerable number of plants had been propagated, when Mr. R. Harkness recognised it in the autumn of 1895, before the Rose was distributed by the celebrated Irish firm. Mr. Piper also notes a further instance of *Souvenir d'un Ami* sporting that beautiful white form of *Souvenir de S. A. Prince*, thus making three authenticated cases of practically, if not actually, simultaneous sporting of this one variety. It is pleasing to note that in neither instance would Mr. Piper distribute when he discovered that similar Roses had already been named, if not sent out. We have far too many duplicates. Other instances are given.

It is pleasant to read the Rev. D. R. Williamson's very favourable opinion of our British-raised Roses as being so suitable for the south-west of Scotland. For that matter, will not the majority of our home-raised Roses grow anywhere almost? and are they not among the very best we have? Newtownards, Waltham Cross, Cheshunt, Shepperton, and other places have given us some grand acquisitions of a hardy nature.

Mr. G. Paul's opening remarks upon ninety-six trebles at Birmingham called to mind that for seventy-two trebles at Brighton, about twenty years ago, a class that exhibitors will not easily forget, especially those who had the task of setting up the blooms, and one who failed to get the "Ashbury cup" by six points was not the happiest man in the world that day. It is a pretty idea, that mentioned by Mr. G. Paul—viz., "A bud, a flower half open, and a fully expanded bloom, so as to afford the public an object lesson of the variety in its several stages." It would be interesting to see this carried out, in spite of the evident irregularity that would inevitably result. Mr. G. Paul has had very great experience in exhibiting Roses, but everybody will not agree that an "equilateral triangle" lacks grace, when we see such uniform stands; always provided the flowers are even throughout, stands of triplets are decidedly imposing. There is surely opportunity for taste in arrangement here as well as where more or less flowers of any one variety are associated. Mr. G. Paul's novel suggestions might well be carried out, as we ought to have something fresh in the way of attraction each year if possible.

"A really good Rose year" is Mr. E. Mawley's opinion of 1897, and no one takes closer note of these seasons year by year than does the hard-working Honorary Secretary of the National Rose Society, whose opinions are made doubly valuable from the fact that he was last year President of the Royal Meteorological Society. To follow through his most interesting record of the past year, month by month, is instructive, while the meteorological observations at the end are by no means the least interesting portion of this annual, which should be in the hands of all rosarians.—EXHIBITOR.

SEASONABLE HINTS ON FLORIST FLOWERS.

IN the beginning of February we generally say the worst of the winter is over, and we may begin to think about our spring work; but this year we have as yet had no winter, and, in fact, the season has been the most remarkable on record. I am writing now of East Kent, where we have not had a flake of snow or any frost worth speaking of. This has been accompanied by generally high temperature and absence of rain. Our springs have not yet risen, the wells on the more elevated portions of our neighbourhood being quite dry, and the cottagers have to go some distance to get water; and yet one reads that in Glamorganshire and Devonshire there were 14 or 15 inches of rainfall in the month of December, while we had but 3.19, and in January only 0.47, not quite half an inch. As yet February gives no indication of earning its title of "fill dyke," and I think we cannot but look forward with some degree of apprehension. We see signs of growth in all directions, and wonder whether the poor things which are now showing themselves and pushing through the ground will receive a rude shock. It has, of course, affected our florist flowers in frames as well as things out of doors.

AURICULAS.

I am afraid grievous disappointment will await the growers of these flowers, for there has been a very large percentage of winter blooming,

and wherever this has taken place all hopes of a good truss from the same plant are at an end. There has been little damp to contend with, and the plants now look well and strong. We used to be very particular about this time as to top-dressing, but that has been almost abandoned, as the more accurate knowledge of the condition of the plants proved it to be unnecessary—the truss has been already formed, and therefore any fresh stimulus was not required. Those who admire big trusses and large flowers may perhaps be inclined to give some liquid manure, but I have always deprecated anything which would interfere with that refinement which forms one of the chief beauties of the Auricula. Little need now be done but taking away all dead foliage and seeing that the plants are free of aphides. Air should be given now on all favourable occasions, and as the plants begin to push they will require more water. Good ventilation and freedom from damp are the two points on which most stress should be laid at this season.

CARNATIONS AND PICOTEEES.

The great change which has taken place with these beautiful flowers still continues, and while in some respects one regrets it, I do not think it can be wondered at. Visitors saw at our exhibitions grand stands of beautifully marked and regularly formed flowers, and they were captivated by the brilliancy of the scarlet bizarre or the delicate edging of the rose Picotee. They must have them and try to do the same. But, alas! although their gardener might grow them successfully, they found that the flowers were not regular, and had nothing of the symmetry that they had admired, and they then found the grower who wished to succeed at the exhibitions must not only be able to grow them well but to dress them. Some petals had to be taken out, and the whole regularly arranged so as to present the appearance so much desired. The gardener naturally thought this beneath him, and the time required would be much more profitably spent on other things. Then came the border varieties and the yellow grounds which Mr. Martin R. Smith, Mr. Douglas, and others have succeeded in raising; they comprise all shades of colour, and are vigorous in growth, and free blooming. Ladies especially delight in them, because they are so good for cutting, so fragrant, so floriferous, and so to a great extent they have ousted in many instances the delightful varieties which were so prized sixty or seventy years ago, and when I have known as much as £2 2s. to be paid for a pair.

There are some growers who make up their beds of these in the autumn, and of course this year they have had an exceptionally good time. I have always maintained, however, that it is best to keep them in pots during the winter. My small collection looks very well; the plants are vigorous, and there is no sign of black spot or mildew amongst them. They will now require looking over, all dead leaves to be taken away, and the surface of the pots stirred. I shall shortly remove mine from the pit where they have been wintered to a more open position, where they will be sheltered from wet, but fully exposed to the air, and in this position they will remain until it is time to plant them.

GLADIOLUS.

It will be rather too soon at present to think of planting the corms, but I notice that some of mine are sending out shoots, and these I shall therefore put into small pots and place them somewhere where they will be free from frost and ready for planting when the proper time arrives early next month.

PANSIES.

These, too, have had a good time in the open, but I am afraid that in the South of England they are not so much in favour as they ought to be. Our climate is too dry, and they seem to rejoice more in the North of England and in Scotland than with us. One well known Scotch firm has, however, begun to cultivate them in the northern part of our county, and if it succeed it will be an encouragement to others to try. I grow a very few in pots, but those who cultivate them in this manner must now see about repotting, using a good mixture of loam, leaf mould, and well decayed manure, with some sand. Here, too, the same change of taste has occurred; the old florist type has now nearly gone out of cultivation, and the Fancies hold the field; they are bold and decorative looking, and are more robust in constitution than the older kinds.

RANUNCULUS.

The ground is now in such splendid order for these that the sooner they are planted the better. The beds have been already prepared, and a dry day is all that is necessary. They should be planted in rows 5 inches apart, 4 inches in the row, and about 1½ inch deep. The one great trouble at present arises from worms, which have an unpleasant way of turning the roots over and throwing them out of the ground. They should be closely watched, and where they are found so served replanted. A little firmness in planting will probably prevent a good deal of this style of injury; it is a great pity that the Dutch florists seem to have lost sight of the old kinds. The beds should be kept clear of weeds, but nothing more will be required at present.

ROSES.

One can hardly as yet say what the result of this wonderfully mild season may have on the prospects of the Rose grower; but at present I have on my wall shoots of Fortune's Yellow 2 or 3 inches long. I do not think, however, as far as I can judge, that those which are in the open are moving more vigorously than one could wish. Of course the most essential thing now is that of pruning, for on this, in a large measure, depends the future well-being of the Rose garden. It is an operation that requires to be carefully and intelligently performed, and it is one which, I think, in most instances, the grower will himself see to, as the special characteristics of the plants will have to be noticed. Hybrid Perpetuals are generally the first that require pruning. The distinction between strong and weak

growers must be carefully observed, as the former require much less of the knife than the latter. Teas may be left for awhile—indeed, it is hardly well to begin the pruning operation before the end of the month or the beginning of March, and the Teas certainly not until a month later, and should severe weather come on, it will be better to postpone it still further, and after this excessively mild season we may, perhaps, have to experience a very cold and trying spring.—D., Deal.

WEATHER IN LONDON.—The mild weather still continues, and save for a light frost on one or two mornings of last week, and a little snow, we have seen no signs of winter. On Thursday, Friday, and Saturday, though dull at times, it was dry, but rain fell heavily on Sunday morning. During the afternoon it brightened, and the sun shone at intervals. Monday was dull with occasional drops of rain, while on Tuesday it was dull with a very little rain. On Wednesday morning it was bright and cool.

— WEATHER IN THE NORTH.—The threatened spell of wintry weather of last week did not last, and there has been no frost since the 8th. The past week has brought a succession of south-westerly gales, some of the nights being very stormy with a good deal of rain. Sunday was very cold, and the hills around had another covering of snow. On Tuesday morning a very high wind was blowing from the S.W., with a dense rainy drizzle, and the thermometer at 49°.—B. D., S. Perthshire.

— ROYAL HORTICULTURAL SOCIETY. — FRUIT FLAVOUR CLASSES.—Mr. W. H. Divers, Belvoir Castle, was first for Apples with Cox's Orange Pippin, and Mr. Woodward, Barham Court, second with Calville Blanche. For Pears Mr. Woodward went to the front with Passe Crassane, Mr. Divers coming second with Olivier des Serres. These results were omitted from our report of the last Drill Hall meeting.

— HORTICULTURAL CLUB.—The twenty-third annual house dinner of the Club was held on Tuesday, the 8th, when there was a larger gathering than on any previous occasion. The chair was occupied by Sir J. T. D. Llewelyn, Bart., M.P., Chairman of the Club. There were also present the Revs. W. Wilks and J. H. Pemberton, with Messrs. Harry J. Veitch, J. Gurney Fowler, J. Hudson, J. Walker, G. Bunyard, G. Munro, C. J. Wise, P. Kay, H. Turner, J. Assbee, J. R. Featherby, A. G. Williams, G. Paul, H. J. Pearson, C. Pearson, P. Crowley, A. Watkins, J. Sweet, R. G. Salmond, H. T. Armitage, R. Pinches, and the Secretary. Mr. G. Bunyard arranged for an excellent selection of instrumental and vocal music to be given during the evening. An admirable dessert was provided by the kindness of Messrs. G. Munro, J. Assbee, and P. Kay, while the tables were beautifully decorated with flowers and plants from Messrs. J. Veitch & Sons. The usual toasts were given, and altogether a most successful meeting took place. The condition of the Club was stated to be very satisfactory, and several new members were added.

— SHROPSHIRE HORTICULTURAL SOCIETY.—The annual general meeting of the members of this Society was held at Shrewsbury last week, in the absence of Lord Kenyon, President, under the presidency of Major-General the Hon. W. H. Herbert. There was a large attendance of members. The statement of accounts showed that the total receipts of the year amounted to £4517 4s., the largest amount yet received. This included £437 13s. 6d. subscriptions, £752 0s. 3d. received at the gate on the first day, and £1825 0s. 10d. received at the gate on the second day. Cheap tickets were also sold previously amounting to £550 18s. 4d. The expenses of the year, excluding the spring show, were £3384 10s. 3d. (excluding special gifts). Of this sum no less than £982 1s. was given in cash prizes, medals, &c. The gross profit on the summer show alone was £1130. Heartly votes of thanks were given to the Worshipful Company of Fruiterers, London, for their splendid medals, the Veitch Memorial Trustees, and the late President, Lord Kenyon, for his special medals, and to donors of special prizes. T. F. Kynnersley, Esq., of Leighton Hall, Salop, was elected President for 1898. Considering the special expenses of the year the result is most gratifying, and almost astonishing. We have heard that grants of £35 were made to Mr. Cypher and Mr. Finch for injury to their plants through the collapse of a marquee.

— GARDENING APPOINTMENT.—Mr. Geo. Hawes, until recently foreman at The Gardens, Lyne, Rusper, Horsham, has been appointed gardener to W. Grazebrook, Esq., Thenford, Banbury.

— KEW GUILD.—The annual general meeting will take place on Thursday evening, February 24th, at eight o'clock, in the Lecture Room in the Royal Gardens. Entrance by the Melon Yard Gate.

— THE GREAT FIRE IN HOLBORN.—We are informed by Messrs. Carter & Co. that the fireproof outer walls of their premises were scorched only, and this particular warehouse contained only a few score bales of breakfast oats, so that orders will be executed and despatched with the usual promptitude.

— NEW "GARDEN BOOK" BY THE POET LAUREATE.—According to "Literature," the Poet Laureate has rented for the winter months the Villa Cedri, in the upper valley of the Arno, about two miles from Florence, and is engaged on a Tuscan sequel to "The Garden That I Love," and "In Veronica's Garden." Many readers of these delightful books will look forward to the publication of Mr. Austin's new book. Is it to be "In the Poet's Garden" or "In a Tuscan Garden"? —A. HARDIMAN.

— UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—At the Committee meeting of the above Society, held at the Caledonian Hotel on Monday evening, it was worthy of note that every member of the Committee was present. Twenty-seven new members were proposed and duly elected on the Society, this being the largest number ever elected at one meeting. The average age of the candidates was twenty-five years. The total number of members is now 714. The annual meeting will take place on March 14th, at which Mr. G. Wythes, V.M.H., has consented to take the chair.—G. W. CUMMINS.

— CHESTER PAXTON SOCIETY.—At the usual fortnightly meeting held in the Grosvenor Museum on Saturday last, Mr. C. Flack of Cholmondeley Castle Gardens read an able and instructive paper entitled "Grape Growing for a Private Establishment." Mr. Flack, who is a recognised authority on Grape culture in Cheshire, dealt extensively with the subject, entering fully into all the details of treatment and cultivation of the Vine, and gave a list of the best and most useful varieties for keeping up the season's supply. An interesting discussion followed the reading of the paper, when it was very evident that several valuable hints had been thrown out by the essayist, which the members would carry away with them and put into practice. The meeting terminated with a hearty vote of thanks to Mr. Flack.

— GIANT MIGNONETTE.—The remarkable looking variety of the common British Mignonette which Messrs. Cannell & Sons have at Swanley under the name of Reseda alba, certainly also should be known as gigantea. Whilst the variety grows somewhat spreading, and is measured by inches in height, this giant variety sends its long spikes up to a height of several feet. It is really a noble garden plant, and the long spikes, gathered and set up in glasses, not only keep fresh a long time, but grow and develop quantities of fresh flowers. Ordinary fragrant Mignonette cannot be endured by all persons in a room; this variety, however, has very little odour. It is, too, very hardy, for on a border where Mignonette Machet was quite dead, the giant form was vigorously green, and full of growth—would, indeed, soon bloom. Plants in pots from seed sown in August ranged from 10 to 18 inches in height, clothed with finely lacinated leafage.—A.

— HANLEY HORTICULTURAL FETÈ.—We have received the schedule of the exhibition that is to be held in Hanley Park, Staffordshire, on July 6th and 7th. It is a substantial and excellent production, and predicates a varied and extensive show. The classes in the different sections exceed 100, the chief being the first on the list, in which £20 and a special is offered as the first prize in the open class for a group of plants, with five others in the same class of £15 (and special), £10, £7 10s., £5, and £2 10s. This ought to bring good competition. For a group of Orchids £15, £10, and £5 are provided, with two specials. We also observe a first prize of £6 and special for forty-eight Roses, and the same for thirty-six triples, with three other prizes following in each class. Prizes of £7, £5, and £4, each with a special attached, are offered for decorated dinner tables in a form that is left entirely to the discretion of the exhibitors. The chief prizes for fruit are £5, £4, £3, and £2 for a collection of six dishes. A pleasant feature of this schedule is the offering of so many special prizes by local supporters of the event. Gold and silver medals are announced for non-competitive exhibitors. Evident Hanley means business. Mr. Joseph Kent, Superintendent, The Park, Hanley, is the Horticultural Secretary.

— EARLY SPRING FLOWERS.—When waiting at Barham Junction the other day a beautiful bunch of spring flowers carried by a lady attracted my attention. It consisted of *Pyrus japonica*, Vincas, Snowdrops, Crocuses, Wallflowers, Anemones, and others, showing how early these lovely spring flowers are this season.—A. O.

— WEEDS SHOWING FLOWERS.—Those who have weedy patches or plots of ground remaining undug may be reminded that vigorous plants of Groundsel will soon be in bloom, and if let alone will rapidly mature a crop of seed, which may be blown all over the garden, causing work and trouble in the future. Dig the ground and bury the weeds to form plant food is the advice of—PRACTITIONER.

— NARCISSUS MINIMUS.—This, the tiniest of all the Trumpet Daffodils, opened here for the first time this season on 24th January. There was only one flower, however; and it is probable that the greater number of the flowers will be more than a week later. These are established bulbs, and have not been lifted and dried. Had they been dried off and replanted early they would probably have flowered sooner. This Trumpet Daffodil is always an early bloomer, and in 1890 flowered a few days earlier than this year.—S. ARNOTT, *Carsethorn by Dumfries, N.B.*

— THE GARDENERS' BENEVOLENT INSTITUTION.—In reply to Mr. Ollerhead, I beg to say, that even though, as I proposed, ballot papers need not be signed, only those to whom sent could have possession, therefore it is absurd to talk about anyone being able to fill them up. Surely it is hardly argument to suggest that papers would be filled up and returned after the subscriber was dead. Papers should be issued only fourteen days before the election, and required to be returned per post, with the votes filled in, two days before the election. Were that so, there would be no canvassing for signed but unfilled voting papers, as is now the case, to be used in bundles at the voting scrutiny for the purpose of making certain candidates having friends at Court safe. Called a ballot, the voting is the reverse of balloting, which my proposal would make it.—A. D.

— LOUGHBOROUGH GARDENERS' ASSOCIATION.—On February 9th, before about thirty members of the above Association, Mr. E. Luckhurst, F.R.H.S., gave a lecture on "Plant Food," referring to the soil, and its proper condition of cultivation, as being the medium whereby all manures were gradually absorbed, and in turn given out to the plants as required for their sustenance. By the aid of a couple of black boards the lecturer was able to display in a concise manner the principal ingredients of "the Luckhurst manure," containing the "essential elements" of fertility. The analyses of stable and farmyard manure, sewage, sawdust, peat moss, and soot were referred to, and the best methods of application detailed in a comprehensive manner. The nitrate fields of Chili, the source whence comes sulphate of ammonia and muriate of potash, were briefly described. The lecturer said, that by a careful and judicious application of manures rotation cropping was not absolutely necessary. Some discussion followed upon the merits of sawdust and peat moss as manures, which elicited responses from the lecturer, who quoted instances of the great increase in the value of land which had for a number of years been manured with these fertilisers by market gardeners. The usual hearty vote of thanks was accorded. [Is there not a mistake in the reference to sulphate of ammonia?]

— TOMATO AND POTATO CULTIVATION IN CHESHIRE.—The results of some experiments in Tomato and Potato cultivation at the Cheshire County Council's Agricultural and Horticultural School at Holmes Chapel have been compiled, and are of great interest. In 1896, when the experiments with Tomatoes were successful, the plants were raised from seed sown in the previous December, and the first ripe fruits were gathered on the following 4th May. It was thought by sowing early, and having large and strong plants, the ripe fruit could be produced earlier in the season; consequently seed was sown at the end of August, and the young plants were established before the winter set in. The result was not quite satisfactory. Ripe fruit was gathered a fortnight earlier, but the yield per plant was considerably less. Good liquid manure is described by the chief of the Horticultural School as still one of the best of fertilisers. The heaviest yield of Potatoes per acre was 17 tons 13 cwt. 2 qrs. 14 lbs., and the smallest 7 tons 12 cwt. 3 qrs. 3 lbs., both of these being late varieties. The early varieties averaged from 10 to 11 tons to the acre, and the second early varieties from 12 to 14 tons per acre. In some of the varieties disease claimed 2 tons 10 cwt. of the yield per acre, in others only a few lbs. of tubers. Small and unsaleable Potatoes varied from 3 tons 4 cwt. to the acre to about 8 cwt. to the acre. The experiments are to be continued next season.—R. P. R.

— **STOCKPORT'S FOSSILLED OAK.**—We referred to this ancient relic a few weeks ago. Some newspaper cuttings have been sent to us concerning it. It seems Mr. Bailey, "a local geologist, whose opinions in technical circles is often sought," has pronounced this tree, the age of which he estimates at some 2500 years, a "male" tree. Mr. James Percival is anxious to ascertain how Mr. Bailey has arrived at the wonderful discovery! and wishes to show him, when Oaks are blossoming, that both male and female flowers are produced by the same tree. "The result of evolutionary process," he may perhaps explain; all the same, determining the sex of a tree that has been buried 2000 or 3000 years does seem a little mysterious.

— **THE BECKENHAM HORTICULTURAL SOCIETY.**—This Society has arranged an interesting course of lectures to supplement the ordinary weekly meetings at which various papers are read and discussions follow. The first lecture took place recently, and Mr. James Martin gave an interesting and instructive discourse on the Gloxinia. The meeting was held in the Public Hall, and the room was well filled with gardeners employed in the neighbourhood. The lecturer reviewed the history of the Gloxinia from its earliest known date, 1739, to the present day. Mr. Martin interspersed his remarks with many witty anecdotes. The chair was taken by Mr. H. J. Jones of Ryecroft. A really charming group of Cyclamens, brought by Mr. T. Crosswell, created much interest, and drew from both Chairman and lecturer the highest compliment for cultural skill.

— **MORDEN GARDENERS' SOCIETY.**—The third of the series of lectures which it has organised this season was given by Mr. H. Alderman, gardener to G. Hatfield, Esq., Morden Hall, Surrey, and was entitled "Practical Hints to Cottage Gardeners and Exhibitors." Dealing with the class for the best kept and best cropped gardens, he gave some sound advice as the general arrangement of the ground and the position of the rows of crops; the bush fruit trees, the rubbish heap, and the clean, tidy effect which should always be aimed at. Then the lifting of crops for show was touched upon. Roots should never be scrubbed, as is so often done, but carefully washed in lukewarm water with a little softsoap in it, and allowed to dry. Exhibitors were advised not to be too much elated at their successes in the show tent, and on the other hand not to be discouraged if they do not take a prize at the first trial, but to remember that those who try again are the winners of the future. A hearty vote of thanks to Mr. Alderman brought the meeting to a close.

— **SQUIRRELS.**—Of the habits of these animals in the matter of Walnuts, as referred to by Mr. G. Dyke, I have no experience beyond observing that they left them severely alone when on the trees, and had little chance of securing any when "hulled." Of all fruits the squirrels prefer Cob Nuts and Filberts, attacking them whilst "milky." They will carry off Nuts for eating at leisure, as they will also Plums, especially Coe's Golden Drop, and even Nectarines from walls. Spanish Chestnuts they sometimes "pie" in the ground, and after a time unearth them, either carrying them off elsewhere, or disposing of them on the spot. The animals also proceed in a similar manner with acorns and Beech Nuts, and appear to be guided solely by smell "in finding the solitary Nuts" or acorns after a period of severe weather. The "instinct" of the squirrel partakes of the cunning of the fox, which kills in abundance in order to carry off and bury solitarily, and thus have a feed another day when fresh food is scarce. The dog buries a bone, the fox a rabbit, and the squirrel a nut or acorn; each animal returns with unerring steps to the deposited article on the pressing demands of hunger. Instinct! It is memory, reason.—G. ABBEY.

— **INSTRUCTION IN BOTANY AND HORTICULTURE.**—It has been arranged by the Department of Science and Art to hold, at the Royal Botanic Gardens, Glasnevin, Dublin, a practical course of instruction in applied botany and horticulture, for the benefit of the young gardeners in training there. Dr. T. Johnson, the Professor of Botany in the Royal College of Science, will give a course of practical lessons in the scientific principles of applied botany, followed by a course under Mr. F. W. Moore, the keeper of the gardens, on horticulture and floriculture, with explanation of the scientific arrangement of plants in the different houses and beds in the gardens. The training offered, says the "Irish Farmers' Gazette," is on the lines of that given in the Royal Botanic Gardens at Kew and Edinburgh, and in connection with the Durham College of Science, as described by Professor Somerville when he pointed out to the Commissioners of Manual and Practical Instruction the need for such courses for teachers of Irish schools. It may be expected that the young men after receiving such a thorough training in both the theory and practice of gardening will be more than ever sought after by those who own fine gardens in this country.

— **FRUIT BUDS AND BIRDS.**—The abnormally mild weather experienced this winter has had the effect of causing early swelling of the buds on Gooseberry and Currant bushes. Birds are not slow to recognise this, and unless some means are adopted for checking them, they will soon entirely strip the bushes. Sparrows are the worst, and with them it seems a question of mischief, as many of the buds are simply pecked off and fall to the ground. Many ways are adopted for scaring them, but sparrows are by no means bashful, and soon get on intimate terms with webbing, shavings, and other scares. One of the best preventives is to mix soot and dry lime together, and thoroughly dust it over the bushes, taking care to repeat the operation if rain washes off the mixture. This renders the buds distasteful to the birds, and also acts as an insecticide, destroying pests and obnoxious growth that infest the trees.—G.

— **GREEN GRASS.**—As another evidence of the mildness of the winter, quite as remarkable in its way as are most of the diverse evidences furnished to the papers, I may mention that the gardener at the County Hall, Kingston, was, on January 31st, mowing the lawn there, and when I saw it on the next day I thought I had never at any time seen grass greener or more beautiful than it was then. How delightful a feature a smooth, clean, well-kept grass lawn is at any time we all know, but I do not remember ever to have seen the grass greener or more attractive than it has been of late. This is a tribute to the mildness of the season that is rather unusual. I have helped in winter grass mowing in pre-lawn mower days by running a scythe over it when covered with hoar frost. How easily it would shave off then, but how clogged would the scythe become. Certainly the grass was shorter afterwards, but it was not too green.—D.

— **ARTIFICIAL MANURES.**—Mr. Dyke must excuse me from following him in a discussion *re* the use of artificial manures. These things seem to be like patent medicines. Everybody has his own favourites in which he believes, and it is difficult to show that the world is one whit the better for them. Artificial manuring as advocated by certain manure vendors is rapidly degenerating into cant, from which I hope to be saved. Such experiments as I have conducted and observed have led me to realise their practical worthlessness. As to killing the eelworm, the latest specific seems to be found in tickling its tail with superphosphates to make it laugh, then choking it with a big dose of basic slag. I have had no experience of eelworm, and amongst my gardening friends, who are good cultivators, the same ignorance prevails. It seems to be very easy in these days to get artificial manuring and eelworm on the brain.—A. D.

— **FISH MANURE AND WEEVILS.**—Recently a market gardener in Kent applied a heavy dressing of fish manure—the putrid carcasses of sprats and starfish—on to a piece of poor land with the idea of enriching it. Soon after the ground appeared to be alive with small brown weevils, very similar to the Vine and Raspberry weevils, which played dreadful havoc with the vegetables which formed the crop. Now the gardener is at a loss to know how to destroy the hard-backed marauders, and questions the advisability of using putrid fish as a manure if it is the means of introducing pests of this kind. In many Raspberry and Strawberry growing districts fish manure is largely used, and the Raspberry weevil is the common enemy, and a hard one to fight. Is this pest introduced in the manure? because if such is the case it would pay Raspberry growers to let it severely alone. Perhaps other readers can throw some light on this matter.—KENTISH MAN.

— **A CAUTION.**—A man called on me a few days ago in answer to my advertisements of businesses for sale, stating he wanted one for his son. I asked him where he came from. He gave an address which I have since found was a bogus one. He described himself as a dealer in cattle staying at the King's Cross Hotel. Then came the old trick, at least to me. In a bland way he said, "I did a foolish thing this morning, left all my money at the hotel except a shilling, which I thought was a sovereign; can you lend me one?" He had in return, "What! Get out quick as you can or I shall help you; this game won't do here." Needless to say he went away quicker than he came. He has paid other people a visit I learn, but with another tale. Should he pay anyone else a similar visit the following description may be useful. Age about fifty-two; height about 5 feet 4 inches; shabbily dressed, bald-headed, whiskers getting grey, cut in short all over his face and chin; good address; limps a little when walking. The only regret I have now is that I did not help him to leave my premises by kicking.—ALFRED OUTRAM, F.R.H.S. [A kick with seventeen stone behind it would be no light matter, and it is not surprising that the would-be swindler "went."]

FLUED GARDEN WALLS.

IN reply to Mr. Geo. Dyke (page 56), I do not know whether there are any of these in use at the present time, but I have had some personal experience with these "ancient flues." Though generally discontinued before then, the late Mr. T. Rivers' work, "The Orchard House," in 1850, gave flued walls their quietus. Only the north wall of the garden was flued, this being about 15 feet in height above the ground, covered on the north side with Morello Cherries, and on the south side clothed with the finest Apricot trees I have ever seen to half its extent, and the other half with Peach and Nectarine trees.

The Apricots appeared to like the wall's warmth and dryness, the fires being lighted every afternoon from the blossom buds beginning to show white, and were continued till the early part of June, when they were discontinued on half the length of Apricot wall, but kept going on the other half till the fruit was ripe. This made a difference of about three weeks in the ripening, so that the Apricot season lasted for something like six weeks. The only kind grown was Moorpark, and the trees neither lost limbs from gumming or borers.

Woollen netting, $\frac{1}{4}$ -inch mesh, was employed to protect the blossoms, the net being let down in the late afternoon and drawn up about 8.30 in the morning, or when the frost, if any, had departed. The protection was continued until the end of May or beginning of June, and at the time of the Apricots ripening finer netting was placed over the trees to keep the wasps outside. Everybody was "sick" of Apricots, even the "lad" who had to look after twenty-four fires at eight o'clock at night when the wall fires were on, so the memory was pretty well impressed, especially when this entailed a journey of about a mile each way, and must be done twice in very frosty weather each night.

The Peach part of the flued wall was treated similarly to the Apricot, the netting and the flues being requisitioned as soon as the blossoms showed pink, half of the wall being fired until the Peaches and Nectarines were ripe, so that a supply was obtained from the end of July till far into October. Early Anne was the first Peach to ripen, and Late Admirable the last. In 1852 we had a Peach and Nectarine on one branch on a previous year's shoot of Red Magdalen Peach tree, and also lots of red spider, the warmth and dryness of the wall fostering the pest, and causing the need of forcible syringings to keep it in check and the trees healthy. On the other half of the Peach part of the wall the fires were dispensed with after the end of May and the trees were less pestered with red spider.

What do I think of flued walls? Well, they were good or bad, just as they were worked. If overheated they did more harm than good, but when used in reason, just a little warmth being maintained, they certainly were an advance on unheated walls, the chief points being not to overheat, but at the same time to protect thoroughly from frost. Finer Apricots I have never seen or tasted than were grown against a flued wall; and in 1851 I saw such a sight of wall Grapes as has not fallen to my lot since. The variety was Black Hamburgh, large, handsome, well-finished clusters, against a wall that was flued. It was my lot also to see on a flued wall Banksian Roses blooming splendidly in the cold North. The first vinery I have recollection of had a flued wall, the heat and smoke from the furnace having to make three runs of the length before escaping by the chimney. The wall was covered with Cactuses in great variety, which bloomed magnificently even though shaded with Vines.

As to the "utility of all the expense, with attendant cost of firing," most of the latter was from cinders from the hall, costing little beyond labour, which was then about half the value it is at the present time, while the necessities, or rather luxuries, of life now, as compared with then, are twice as cheap, excepting butchers' meat. The endeavour in those days was, as regards firing, to get as much heat as could be extracted from the smallest quantity of fuel and retain it as long as possible, whereas in these times the principle appears to rest on getting the most heat in the least time, regardless of bulk in consumption. When I took the pen in hand I had no idea of running beyond a few lines, but to go back something like half a century brings to mind many things, some of which a few, if not many, readers may think ought not to be entirely lost.

Reverting to the query about these "ancient flues in garden walls." In the past they did good service, and are capable of still better in these present days where flues (unused) in walls exist. Cover the walls with glass, heat the structures with hot water, and connect the furnace flues with the old ones which run along the wall. Thus may the past be linked with the present on the sound principles of utility and economy. I know the ideas are ancient, but they are sound and substantial. The old flued garden walls securely coped, only need the magic wand of the horticultural builder to form first-class fruit houses on their southern aspect, growing the Vines or trees in a form that will permit of the wall surface being utilised to the fullest extent. There is no need to go to any great expense, only let the structures be like the wall—sound and substantial, then both the houses and wall will give a good account of themselves under judicious management.—G. ABBEY.

CORDON GOOSEBERRIES AT STONELEIGH ABBEY.

THE methods adopted in the culture of Gooseberries on trellises in these gardens are as follows:—

1, SOIL AND SITUATION.—Our soil appears to be admirably suited to this fruit; in fact, any good soil on a dry gravelly bottom will suit the Gooseberry. The situation must be open and well exposed to the sun, or the results will be altogether unsatisfactory.

2, PROPAGATION BY CUTTINGS.—Stout, healthy, young shoots should be prepared early in the winter season; these ought to be about 15 inches in length. All the buds must be cut out except a few at the top of the cutting, in order to prevent the production of suckers. The cuttings should be laid 4 inches apart in drills, about 1 foot asunder, in a partially shaded situation, there to remain till the following year; they may then be transplanted about 18 inches apart each way. The next year they may be planted in their proper position. In the event of the cultivator desiring an immediate effect, plants from two to three years old may be purchased and planted in position at once. In this case, unless cordon trees can be obtained, the side branches must be pruned back to within 2 inches of the main stem, leaving the strongest and most central shoot as a leader.

3, PLANTING AND PRUNING.—The trellises here are 150 feet in length and 5 feet in height, with wires 6 inches apart. These should receive a coat of paint, as well as the posts to which they are strained. The plants, when the leaves fall, should be inserted 10 inches apart and made firm, afterwards tying them neatly to the wires. Pruning may be done at any time from the end of November to February, though I prefer to do it as early as possible, cutting the shoots back to three or four buds—i.e., spur-pruning. When the prunings are cleared away, a dressing of good manure is spread over the roots and carefully forked in.

4, SUMMER MANAGEMENT.—The side shoots are shortened twice during the growing season, and careful attention is given to watering. It is good practice to apply a mulching of manure early in season, allowing it to remain throughout the summer for the purpose of retaining moisture.

5, INSECTS AND DISEASES.—The caterpillar is perhaps the most formidable enemy. If prompt measures are not taken on its first appearance not a leaf will be left on the trees. The means that have been resorted to for the destruction of the pest are legion, but I have found none so effectual as hand-picking. Forking the soil is, I believe, of great advantage, for there the chrysalids lurk, and may be too deep for the emergence of the sawfly which deposits the eggs. The red spider in dry seasons is very injurious. This may be kept in check, and possibly eradicated by syringing frequently with spidicide early in the season, otherwise the fruit will be flavoured with it. We also use the hose frequently and heavily, well wetting the under side of the leaves.

6, LIST OF VARIETIES GROWN.—For early picking, Crown Bob, Whinham's Industry, Whitesmith, and Golden Drop; for late picking, chiefly Warrington, and a few of Pitmaston Greengage. The later varieties we also grow as cordons on a north side of a wall, and by protecting with nets placed double thickness, the supply of fruit is prolonged considerably. I was able last season to send Gooseberries to table for dessert as late as the beginning of November, when they were greatly appreciated. The Gooseberry grown by this method will produce much finer and better flavoured fruits than those produced in the ordinary way on bushes.—H. T. MARTIN, *Stoneleigh Abbey*.

A CHECK TO THE FLOWERS.

WE see frost and snow come now with mingled feelings. So mild has the season been until the first week of February that we had begun to cherish the thought that the garden would escape its usual trials. To those who love the outdoor flowers frost and snow are like sickness; perhaps good, but none the less unpleasant. They may be good for the flowers, but to those longing to see once more the faces of their favourites, they are unwelcome visitors. Their errand may be a kindly one in the long run, but for the time they seem to bring it with biting words and unkindly ways. We can hardly dispute the truth of the words of those who tell us that we had better have frost now than later, but, after all, what poor comfort it is! Instead of the flowers of the Arabis we have patches of snow. Instead of the fresh green of the mountain side we see it white to its base. We see around us the springing flowers checked in their growth by the cold, and we long for the gentle breezes which will once more bring with them the renewed uprising of the flowers. Yet we need not be ungrateful for our present pleasures, nor repine that they are fewer than we would wish. There is much to see, much to give heart, and much of which to tell.

The Snowdrops are with us, and they, at least, suffer not in beauty when compared with the purity of the snow. Of those in flower we may select a few for notice. The tallest amongst them all is *Galanthus nivalis* Kilkenny Giant, one of Mr. Allen's. Though in light soil it is, as measured to-day, a foot high, and this is in the open—not drawn up among other plants, but allowed to grow to its ordinary height. The flower is hardly in keeping with the stature so far as regards size, but the height at which the flowers are borne makes them unusually conspicuous. Near it, and planted purposely so by way of a contrast,

is another of Mr. Allen's Snowdrops; this is *G. nivalis* Tom Tit. It has not been in flower so long as Kilkenny Giant, and its stem will probably lengthen out, but it only measured $1\frac{1}{2}$ inch to-day, so that there is a great difference in the appearance of the two. Tom Tit has small flowers, which are quite in proportion to the whole character of the plant. With all its dwarfness of growth and smallness of flower it is, withal, a pretty little Snowdrop. *G. robustus* is again disappointing, and considerably inferior to the Cassaba Snowdrop, or many other species or varieties of this favourite flower.

The Crocuses now begin to come thickly and quickly. The Dutch varieties are not yet fully represented, but among the earliest is Albion—but the striped, not the purple or blue variety. It is a fine Crocus, less plainly striped than many, but with a deep, dark zone at the base of the outer side of the outside segments, which looks very pretty when the flowers are closed. Just at its best, perhaps, is *C. Tommasinianus*. Its name is a long one, but the size of its flowers is not commensurate

delayed by working a little peat and sand into it, there is nothing but propagation to be depended on for insurance against loss. This should be attended to as soon after flowering as possible. A dry, sunny position is generally recommended for Burser's Rockfoil. This advice may be too literally carried out. The soil must not become too dry in summer, or the plants may be lost. This season has not been a good one for *S. Burseriana* in my garden. The pretty *S. apiculata* is now very pleasing with its primrose yellow flowers, although these are not so numerous as in some former years. Had we had a little more sun this Rockfoil would have been exceedingly attractive. The close growth it makes, its early habit, and pretty little flowers make it a favourite with me.

Hepaticas are very bright, and are always seen at their best when the sun shines. It is then that their bright colours are seen to most advantage, as the blooms are raised and opened full to the sunlight. Of course in bloom I think *H. triloba splendens* the most brilliant of

FIG. 22.—CORDON GOOSEBERRIES AT STONELEIGH ABBEY.

with that of its appellation. Although not large they are pretty, and a small clump is very attractive when in bloom. The flowers are described as "sapphire-lavender," and colouring is so difficult to describe, that we may content ourselves with the definition given. It is, however, a variable species in shade of colouring, and bulb dealers who keep such special flowers as these are selecting and naming the various shades; yet it is possible to procure these among a dozen or two of flowers from seeds or from corms from which the various shades have not been selected. The flowers of *C. Tommasinianus*, when in an unopened state, are long in shape, and vary in colour from almost white to nearly purple. The variation in the inside of the segments is not so marked, but ranges from pale lavender to purple. Except in the case of those which are nearly white outside, the flowers have a peculiar "grained" appearance when unopened.

The early Saxifrages are always interesting, and in bright, wintry weather the varieties of *Saxifraga Burseriana* are very beautiful with their white flowers and sharp-pointed leaves. Charming little tufts do these plants form, and it is unfortunate that frequent division is necessary if we are to keep up our stock. *S. Burseriana* begins to die off when it becomes large, and although the death of the plant may be

all. I am inclined to the opinion that there are fewer blooms on these this season, and a circumstance one is disposed to attribute to the character of the weather in autumn.

Iris reticulata and its varieties are comparatively late, and even *histrioides* has been unwilling to unfold. The ordinary green-spotted Snowflake is in full bloom in a sheltered corner of the rock garden, but the form with the yellow spots is only above the soil while the one with several flowers on a stem is still in full blow. *Scilla bifolia*, as represented by a variety from Broussa, is in full flower also, though the other forms are in this, the second week of February, not showing colour. *Scilla sibirica* is in bloom in several places, and the Winter Aconite contrasts well with its dark blue flowers. The Dwarf Almond—*Amygdalus* (*Prunus* of "Index Kewensis") *nana*—is almost ready to open, and there are Primroses almost "galore," *Sisyrinchium* and *Cyclamens*. *Anemones blanda* and *coronaria* are in bloom, and *A. appennina* will follow soon. Grape Hyacinths are sending up their spikes, which before long will entice us with their beauty. As I finish the rain has come again, and, with the check removed, we shall soon rejoice with the "dancing Daffodil" and the many other flowers which come with the spring.—S. ARNOTT.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

WE are now very near to this Society's annual members' meeting. Very much hinges on that meeting. Until there is a great rise in the intellectual and social status of the Committee, it is rightly felt that the Society must remain, as at present, a mere accessory to the Westminster Aquarium. That is indeed a most deplorable position for a Society that aspires to be regarded as National to occupy. The present executive is too much of the earth—earthy. It represents far too much for the good of the Chrysanthemum, either mere trade or exhibiting interests, and so far as the trade is concerned also by selling space incites unfortunate jealousies. It is still farther much too large a body to be productive of good. At present it is the slave of wire pullers. Will the annual meeting do anything to improve this state of things, or will the members be but of the same clay as their representatives? No doubt it is in this direction the Aquarium advocates look for salvation. If the members resolve to clear out of the Committee all retiring members who will not declare against the Aquarium, and put into their places men who will so declare, they will perform great, good service. Still farther, they should, if it be their desire, carry a resolution calling upon the executive to close their connection with the Aquarium at the end of the present year. If not prepared to adopt such action as this, then best leave the matter alone, and admit that protests are but fizzles. Members must be firm and independent if they will not be sat upon and dragged by the tail that wags the dog.—K.

A GARDEN DRAMA.

I HAVE had a mysterious communication. It is couched in the form of a play. What worries me is its ambiguity. In the hope that some sympathetic friend will be able to read the enigma for me I give this puzzling drama (which is short) in its entirety. Communications of an elucidatory nature may be addressed to me, care of the Editor, who will forward them at once.

"MUM'S THE WORD."—A PLAY IN THREE ACTS.

ACT I.

SCENE.—A secluded glade in Euphorbia Park.

(Enter CLOAKED CONSPIRATORS).

1ST CONSPIRATOR: My stature's short, but my determination's great
This enterprise to further. A thousand stalwarts—

2ND CONSPIRATOR: More, man!—of MAN-like action!

1ST CONSPIRATOR: Ay, such, indeed. But soft! thy meaning I perceive. More MEN I want.
A thousand stalwarts, thou wouldst say, and more
Support me. 'Neath the heel of trading syndicate
The Golden Flower of Liberty is crushed.

3RD CONSPIRATOR: Shea-me! And shame it is.

1ST CONSPIRATOR: Alas! 'tis true. Her devotees foregather
In clannish, misty halls, where fighters reign,
Where acrobats, performing dogs and serios shrill
Their antics do perform. Shall this thing be?

ALL:—No!

1ST CONSPIRATOR: Amen to that. Downward the glove is thrown
And I the challenger. Now the time approaches
When battle must be given. Neither knight
Nor cleric militant shall turn me from my purpose.
My blade is whetted. Sword of belted earl,
Mace of bishop or of dean—

2ND CONSPIRATOR: Pardon the interruption, saidst thou dean?

1ST CONSPIRATOR: Ay, dean or bishop, earl or duke, must fall
If in the path of progress he should stand.
I'll take no nay. The Flower of Liberty
I'll raise aloft, and beneath—soft, give me your ears—
I'll build a treasure house for the Reserve.
Say I well?

ALL (impressively): Excellently well.

1ST CONSPIRATOR: Good! Now if success shall crown us we must hasten
Our plans to make. We must be circumspect,
Our goings and our comings must—

4TH CONSPIRATOR (starting): Ah! What sound was that?

1ST CONSPIRATOR: Peace, pale friend, I name no names, now gather round
And hearken.

(Left conspiring.)

ACT II.

SCENE.—The Royal Piscatorium.

(Two men are conversing.)

1ST PISCA-TOREADOR: Patience! sayst thou? Patience! and I thus bearded!

2ND PISCA-TOREADOR: Why, ay; patience is what I said. Look you—

1ST PISCA-TOREADOR: I will not. Shall I meekly bend, in my ripe wisdom,

To insolent criticism? What, forsooth, am I
That I should yield to clamour?

2ND PISCA-TOREADOR (drily): What art thou? Why, a secretary.

1ST PISCA-TOREADOR (proudly):—Nay, a dictator! Honorary, please.
Obedience I claim and will enforce
To my behests. Should they dare breathe defiance
I will hurl a threat of resignation.

2ND PISCA-TOREADOR: Patience, I say. What if they accept it?

1ST PISCA-TOREADOR (uneasily): Accept it!

2ND PISCA-TOREADOR: Ay! What then?

1ST PISCA-TOREADOR: Accept my resignation! Part with me! 'Tis monstrous

Such thought to entertain. Nevertheless, now I think on't
I will discretion summon; for I have heard a whisper
That impious minds are plotting my defeat.

ACT III.

SCENE.—A room at the Handy-Andy Hotel.

CONSPIRATORS, PISCA-TOREADORS, GARDENERS, JOURNALISTS, &c.

1ST PISCA-TOREADOR: By favour of this meeting a report I'll read
Of wondrous progress made in this our work.
Two score years ago and more an inn obscure
Our habitation was. The golden flower languished,
Cold-favoured by the public. But time has passed
And wondrous transformation has had place.
A strong hand led us on our devious way
To fortune. When cold in death that warrior lay
His task devolved on me. Have I performed it well?

(Conspirators whisper together.)

1ST PISCA-TOREADOR (pleadingly): Survey the glorious page of this our history,
The numbers of our army, its equipment.
Some there are who do contend the price of triumph
Is too great. They say we are no army, but a rabble
Driven to dark halls for our exhibitions,
Bound hand and foot to entertainers of the fickle crowd
To whom we are a yielding and ignoble tool.

CONSPIRATORS: Ay, 'tis true.

1ST PISCA-TOREADOR: Nay, 'tis false. None but I know the truth.
None so well as I appreciate the sacrifices
Made on our behalf.

CONSPIRATORS: For dividends.

1ST PISCA-TOREADOR (horried): Dividends! Ah! drive that loathsome word away.
'Tis on philanthropy we take our stand, that
And nought else. Are there in circles horticultural
Souls so base as to imagine that our union
Is one of gold?

1ST CONSPIRATOR: Do you resign?

1ST PISCA-TOREADOR (evasively): Resign? Who spoke of resignation?
The word is strange
And unfamiliar.

1ST CONSPIRATOR (ironically): Welcome the coming, speed the parting guest.

1ST PISCA-TOREADOR: I read not riddles. My words are plain.

1ST CONSPIRATOR: Quite plain. You spoke of private knowledge
And of resignation. Friends, I make a proposition.
Our officers keep information from us, give us threats.
Let's change our officers. I have supporters here
A solid phalanx, sworn to give me help
In this emergency. Give signs, I pray you,
That we are resolute to have our will. (None move.)

1ST PISCA-TOREADOR (in triumphant aside): The big braves hang back

Now that the crucial hour has come. I win!

The day is mine. (Hums away elated): What a pack of fine fellows they are! Tra-la!

1ST CONSPIRATOR (bitterly): And am I thus deserted in my hour of need?

Am I indeed left to bear the brunt of battle

Alone? Is this shame possible? Alas! in olden time

I have the same experienced, yet I thought

A bolder British spirit now prevailed. Here's for Euphorbia—
And oblivion.

CURTAIN.

(Exit.)

—A MUMMER.

CHRYSANTHEMUM NOTES.

MUCH has been written in the Journal of late as to the "best" selection of varieties for various purposes. No doubt valuable information is thereby obtained by those who have not the personal knowledge requisite or the opportunity of judging for themselves. Of course there is no such thing as a "best" selection; the choosing of varieties is purely a matter of personal taste. I note, however, and with pleasure, that there is a strong tendency towards selecting varieties possessing points of "quality." Some writers may feel inclined to join issue, and inquire, What is "quality" in a Chrysanthemum bloom?

My definition of "quality" is somewhat after this style. A bloom of the Japanese section should not measure less than 7 inches in diameter; if it were 2 more it would be all the more desirable. A proportionate depth should be present of, say, 5 or 6 inches. The florets ought to be flat, ribbon-shaped, or slightly turned under at the edges. There must be no sign of an "eye," neither must it be possible to see between the florets on to the board when staged. The colour should be as decided as possible, and as pleasing as one would wish to see. Such is my ideal of a Japanese Chrysanthemum. Some persons will differ, no doubt.

New varieties undoubtedly are the life of the interest in the Chrysanthemums. If the introduction of new forms were to cease for a time interest in the flower would decrease also. There is an innate craving in the mind of man for something fresh, new, or what we do not already possess. Now that English cultivators have taken up the raising of new varieties we hope to see them produced on some defined basis. The intercrossing of varieties will perhaps be done on some scientific basis for the production of fixed and desirable colours. At present the hybridisation is done on haphazard lines.

Societies might do much to encourage the introduction of new and improved varieties by the offering of prizes for those introduced within a given date. It is surprising what a stimulating effect the prospect of winning a prize has upon intending exhibitors. In support of this suggested idea I need only allude to the magnificent results obtained at some shows by the offering of handsome prizes for cut blooms staged in other than the orthodox plan of cups, tubes, and stands. Only a few years since any other idea was out of the question; yet see how much has been done at Edinburgh, Hull, the Royal Aquarium, not to mention smaller shows, the committees of which have been bold enough to strike out a new line for themselves.

The question of "sports" in Chrysanthemums appears to be on the wane amongst cultivators, writers, and "scientists" generally. The reason for this is apparent. While we can procure all that is required on such easy terms—I allude to seedling-raised plants—it seems too much to expect the "ordinary" gardener or Chrysanthemum expert to trouble with the origin of "sports." There is, however, no denying the fact that in certain sections the best varieties have been obtained as the result of "sports." Certainly, amongst the incurved, seedling forms are seldom so consistent as the freaks of Nature. If we could have some light thrown upon the origin, cause, and effect of "sports," who knows but that we might improve considerably upon Nature's endowments!

To the true lover of Chrysanthemums in all its phases and forms the free and ever reckless manner in which new varieties are added to the incurved (?) section is anything but pleasing. It cannot be disputed that of late years varieties have been most liberally added that ought not to be classed as typical forms of the section so much prized twenty years ago. It is quite true that in a few more years there will be fewer specimens seen at shows than even now. Introducers are not blameless for this falling off. Too many sorts have been added to attempt to increase the waning popularity of a section at one time so desirable.

There is no doubt that the cultivation of Chrysanthemums for purely decorative purposes during the last two or three years has greatly increased. Especially are the late-flowering varieties appreciated. This phase of the subject might well and profitably be attended to yet. The Queen, recently alluded to in the Journal, is decidedly an acquisition for late use. At the time I write, February 12th, we have really attractive blooms of this on plants that were flowering freely at Christmas.

The out-of-door flowering varieties of Japanese, such as Roi de Précoces, Comtesse Fouchier de Careil, Ryecroft Glory, and numerous others, are desirable, and might well be added to. These varieties open during October and the early part of November out of doors, at a time when the bulk of the ordinary border plants are over. This is just the class for the amateur to cultivate who is desirous of having a supply of bloom, and has not the means of cultivating the ordinary November flowering sorts.

Just one sentence about single-flowered varieties. Many times I have written in favour of this delightful section. I am pleased to find such writings have had the desired end. For the decoration of the dinner table, vases in rooms, as well as the conservatory in a growing state, no class can put them in the shade. The variety, too, is almost inexhaustible, both in colour and form. Especially bright are some, rendering them all the more desirable.

I do not think the most exacting critic of the Chrysanthemum as an exhibition flower can maintain that there is any decline in popularity of the autumn queen. True, we now and again hear of a society compelled to abandon its exhibition; on the other hand, though, accessions are made. Several horticultural societies within my knowledge have had to discontinue summer exhibitions, and rely exclusively upon the Chrysanthemum as a means of filling their coffers. It is to be expected that extensive shows like Birmingham, Hull, and Edinburgh will attract huge crowds. When, however, we consider a quiet city like Winchester, for

example, that struggled hard to make summer meetings a success, and failed, then confining their energies to the establishment of an autumn exhibition, it says much for the Chrysanthemum as an allurement of thousands of persons who now annually flock to see the fine show annually held in the Guildhall.—E. MOLYNEUX.

LEAF RUST FUNGUS.

I TAKE the liberty to send you herewith in a box some leaves from freshly rooted Chrysanthemum cuttings taken from several different varieties, which are all more or less affected, as you may see, by the *Trichobasis chrysanthemi*, or "fungus rust," so fully described by your contributor, Mr. Abbey, in last October's issues of your Journal. It might be useful to submit these leaves to Mr. Abbey, and I am sure many of your readers would, like myself, be interested to hear from him whether between last autumn and the present time he has been able to come to any definite conclusions as to the character and mode of propagation of this plague and as to the cause of it, as well as the best way to prevent its appearance; further, whether the present examples present any different characteristics to those submitted to him last autumn.

For Mr. Abbey's information I may add that out of over 200 cuttings rooted separately in 2-inch pots, and all placed together in shallow boxes in a greenhouse, only some twenty-five have, so far, been seen to be affected by the "rust." These twenty-five are all new varieties, and come from two nurseries which are admitted to have been affected last season, but the rest of my batch, though all placed close together (and coming mostly from my own plants and a few from friends) are quite clean. The cuttings, even those worst attacked, are otherwise growing strongly and sturdily.

I am inclined to think that the cause of the disease is to be found in the fact of new varieties being forced on to supply cuttings to meet the demand—in other words, that it is constitutional, and it would be useful in this regard if it could be ascertained whether the varieties most attacked in the different parts of England, in New Jersey, Italy, France, or elsewhere, did or did not all emanate originally from one or two sources, and whether the said varieties were mostly new. If yes, this would tend to confirm my view.

I think you will agree with me that this is a subject which deserves serious study and consideration from all horticultural authorities, especially those having the means and facilities for collecting reliable data on the matter, and subjecting the disease to scientific and chemical examination.—J. G. MILLS.

P.S.—I would like to make one other suggestion—i.e., that you should invite through your columns information from the best known amateur growers of show plants on the one hand, and from large growers of cut flowers for market on the other, as to whether they have, last season or this, seen the rust amongst their plants, and, if so, on what varieties. Since writing my letter I have been told by a market gardener that some years ago the same or a similar disease appeared on *Pelargoniums* after several seasons of eraze after new varieties, and that the plants had all to be thrown away, and it was only after some considerable interval that more new varieties could be raised.—J. G. M.

[Both amateurs and growers of Chrysanthemums for market are perfectly at liberty to communicate information of the nature above indicated, but as a rule the last named do not seem to have much time for pen exercise. They are about the busiest men we know, and as a body rank among the ablest cultivators in the world. Mr. Abbey's observations on the leaves that were sent to him are appended.]

The leaves submitted by Mr. J. G. Mills are all infested by the Chrysanthemum leaf rust fungus. Since last summer I have gone into the allied forms of rusts, the nearest being that found in this country on the "Hardhead" or Knapweed (*Centaurea nigra*), which produces telento or resting spores in abundance; but it does not appear to take to the Chrysanthemum. Of the common Tansy (*Tanacetum vulgare*) leaf rust fungus (*Puccinia tanacetii*) I have not been able to secure fresh specimens to test its effect on the Chrysanthemum. I should like specimens of Tansy leaf rust for experimental purposes. I believe the Chrysanthemum leaf rust fungus (*Uredo chrysanthemi*) to be a new species of American origin. Both in the United States, in England, and in Italy it first appeared on the variety Niveum, raised in America, and from this it spread to others.

There is no evidence of the disease being distributed on cuttings or young plants before the spring of 1897, or of its general prevalence before the late summer and autumn of last year in either the Old or New World. The forcing system, both as regards raising new varieties and getting up stock, may have something to do with the breaking out of the disease, as whatever weakens the plant lays it open to readier breach by the enemy. Some varieties have naturally hardy constitutions, and hence are better able to resist the inroads of parasites; and even these resistant varieties may be so weakened by cultural treatment, such as the undue forcing of growth for stock, close and dull conditions for rooting and forwarding young plants in over-rich soil, as to produce unresistant growth.

The study of "rusts" is another question, and I regret to say one of the least understood, as regards preventive and remedial measures, of all fungoid diseases; but they all lead very practical and definite lives. That of the Chrysanthemum leaf rust is from a spore (not having a butterfly existence, as commonly supposed, but capable of hardening or being hardened in integument, so as to exist for a considerable time), to put forth its germ tube in presence of a soft glow of moisture and nutritive medium, not on anything, but upon a Chrysanthemum leaf, mostly failing if on the upper side to effect an entrance, as the cuticle is too hard;

but on the under side, either pushing through a stoma or boring through the epidermis. Once in, the germ tube pushes its way by sheer force of growth in the tissues, abstracting the contents of the cells and multiplying its threads or mycelial hyphæ in a very determined manner. In hard tissue it makes little headway, the spots being small, and the leaf not relatively so much injured as when the leaf is fleshy and soft. In the large leaf the hyphæ strikes deeper and the pustules are larger, often covering the under side of the leaf surface with brown spores. Every one of these spores, no matter whether from the small pustule or the large one, is capable of continuing the plant, being, in fact, a part of the parent endowed with all its inherent properties. It cannot, however, reproduce anything but itself.

The cultivator can do something to ward off the attacks of the parasite upon the assumption that rust arises from weakness of plant—the inducement of in-and-in breeding and forcing of stock, indifferent nutrition, and improper treatment. The hardier variety or the sturdier cutting has the best chance, and the plant duly supplied with silicates, grown steadily under full light and air, will have stouter cell walls, all knit together in the most effective manner for defence. There may not be any disease in such case, but there arise circumstances over which the cultivator has practically no control, such as those of the elements in respect of wet or sunless weather, and then the rust appears, but it could not have come without spores to produce it. Against their germination we should not only fortify the plant on strict hygienic lines, but protect the foliage by a coat of mail.

The cuttings would never have had rust had they been protected by dipping before infection in Bordeaux mixture. True, they may have been infested when received, then when disease appears, use repressive measures promptly. The fungus is the whole and sole thing to get rid of, and only killing will do it. Treat the cuttings with a fungicide, old rusted and badly affected plants burn, giving no quarter to the enemy. Fungicides need to be employed where the fungus enters the plant—namely, by the leaves, mostly from the under side. The disease is not taken from the soil by the roots.

If growers of Chrysanthemums will neither use liquid nor powder insecticides early and systematically, they may become growers, not of clean plants, but producers of myriads of spores of the minute though destructive parasite. It seems desirable that raisers of plants for sale should pay attention to this matter alike in their own interests and for the general well-being of the "Autumn Queen." Its enemy is with us—of that there can be no doubt—and will increase and multiply as the Potato disease fungus did, and does, under favourable conditions for development. —G. ABBEY.

THE LATE BELFAST CHRYSANTHEMUM SHOW.

I HAVE just read with interest Mr. Peter Brock's notes on the above show in your issue for February 10th, and as it concerns myself I shall be much obliged if you will kindly allow me a little space for my reply. Firstly, I am at one with Mr. Brock when he states that the valuable prizes offered in the big class were a great attraction. They undoubtedly were. Probably some of the best blooms seen last year were staged at that fine show. No less than fourteen stands of forty-eights competed, including some from our best English growers.

Secondly comes the disputed point relating to Mr. Mease and the sport from Madame Carnot which he staged in his second prize stand. Mr. Brock states that it was a case in which some judges would not have hesitated to disqualify according to the reading of the schedule, which stated that all varieties must be in commerce. I am not so sure about that. I may state that I was the sole judge in this big class. Anyone acting as a judge, I care not what in, undertakes a very responsible duty, and unless one is absolutely certain before he does so, he has no right to disqualify; far better give the exhibitor the benefit of the doubt. I do not for one moment pretend to be a perfect judge, far from it, but I do claim to know something about Japanese Chrysanthemums. I can tell Mr. Brock that we grew both Yellow Madame Carnot, supplied by Mr. H. J. Jones, and George Warren, from Mr. Wells, and he may be surprised to know that with us the Yellow Carnot came about as pale as the flower shown by Mr. Mease, and how could anyone justly disqualify a bloom simply because it was pale in colour the first year it was in commerce? Is it not a fact that in nearly all cases the colour varies considerably in Chrysanthemums? As examples, take Etoile de Lyon or Vivian Morel. At the late big show of the National held at the Royal Aquarium I believe that Mr. Mease showed the same variety as Yellow Madame Carnot which received the prize as the best Japanese bloom in the show, and it was passed as such by two of our best judges.

I will, as near as I am able, relate the facts of the case at Belfast. In going through the stands, to ascertain if the exhibitors had complied with the rules as to the varieties staged, I passed the bloom in question as a poor specimen of Yellow Madame Carnot without reading the name, so that Mr. Brock will allow I must have considered it something like Yellow Madame Carnot. During the early afternoon a protest was lodged with the Secretary, as Mr. Mease's assistant had labelled it primrose sport of Yellow Madame Carnot. Now, on the face of this it certainly looks like a clear case of infringement of the rules. Mr. Wells, of Chrysanthemum fame, came to me, and said it was entirely his fault; he told Mr. Mease's representative to name it as he did, at the same time saying it was the variety catalogued by Mr. Jones. Mr. Mease's man confirmed this, stating he should have named it, as instructed by Mr. Mease, Yellow Madame Carnot. Now, under the circumstances, believing as I did the case was a pure mistake, I would not consent to disqualify. At the same time, I do not pretend to say there are not two, and probably three sports varying in shades of colour. I shall be glad to

hear what Mr. Mease has to say on the matter. I may mention that I have had no communication with Mr. Mease, either direct or indirect, since the show respecting it.

Thirdly, Mr. Brock complains about the cardboard used in the third prize stand. If Mr. Brock had a clear case here, why, may I ask, did he not protest at the proper time, and not bring up a matter of this kind months after the event, waiting for someone else to do what he was not anxious to do himself? But, if of any comfort to him, I may say that, cardboard or no cardboard, the third prize stand would have received the same award from any responsible judge. I much regret this little friction. I can conscientiously say that I acted quite impartially, taking the greatest pains in making the awards, and I received nothing but kindness from the able Secretary and other officers of the Society, as well as many gardeners, both Irish and Scotch.—EDWIN BECKETT, Aldenham House Gardens, Elstree, Herts.

[We suspect there are few more competent judges of Japanese blooms than Mr. Beckett, and none more conscientious. In such important classes we should have thought that two competent judges would have been engaged. An individual judge may be so absorbed in the work of adjudication as to overlook for a moment the exact terms of the schedule.]

COLLARETS AT THE BELFAST SHOW.

MAY I be allowed to remark *apropos* of the "Belfast Chrysanthemum Show Reflections," page 122, that though late in coming they are better late than never. The facts as related by your courageous correspondent, so far as the cardboard collarets were concerned, are exactly such as were related to me by an independent gentleman who went, and saw, and returned disgusted that such things were permitted, and not only permitted, but apparently effected their purpose of gaining points.—PADDY.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE monthly meeting was held in the Society's room on Wednesday, the 9th inst., when Mr. W. H. Winter read an essay on "Plant Life." He referred to the varied phenomena of the vegetable world, such as growth, food, fertilisation and propagation, and explained the cellular tissue of plants, the principal organs, root action, circulation of the sap, and other matters relative to the subject. There was a good attendance, and at the close of the essay a very interesting discussion was taken up by a number of the members, when much valuable information was imparted. The floral exhibits for professional members were Tulips in pots, which produced a good number of competitors. Mr. S. Lomas secured first prize, Mr. Chas. Scott second prize, and Mr. Thos. Brewer the third prize. The exhibits for amateurs should have been pot plants in bloom, but to the surprise of the officials not a single exhibitor turned up, probably for the first time since the establishment of the Society. Messrs. W. Artindale & Son of the Sharrow Vale Nursery exhibited, not for competition, three large tubs of Tulips. They were of three varieties, and so good that the judges awarded them a cultural certificate. The introduction of new members and a vote of thanks to the essayist closed the meeting. Mr. John Haigh presided.

HONOURS DIVIDED.

IN spite of Lord Chesterfield's aphorism, "There never were since the beginning of the world two cases exactly parallel," we find the Chrysanthemum in the matter of big blooms supplying, apparently, the missing link; and another fact for our law givers and dispensers to face. That there can be no better than the "best" goes without saying, and when the judges award dual honours, or, rather, split the premiership as previously related and commented upon on page 122, we must admit that either their perceptive faculties were at fault or that the paragon of polite teaching was not infallible.

Assuming for all practical purposes that the blooms were of equal merit so far as human judgment could discern, and that not even the wisdom of Solomon could have settled the matter more wisely, the question still asserts itself, Which was the "best bloom" in the show? According to my interpretation of the simple scheduled dictum, the "best bloom," there was none, for on the same line of reasoning it is possible if not probable that occasion may arise when three specimens may claim division of the honours; and, although the possibility may be remote, and the probability infinitesimal, it is not sufficient to exclude four "best" (?) blooms. Still, I take it that neither the wording of the schedule nor the sense of it admit of any such interpretation, and in the matter of what has occurred, assuming, of course, that the points of merit were equal, there was no "best bloom" in the show. Hard as it may appear in dually discounting extraordinary merit, the arrival at that decision, which is logically a just one, would appear to be the correct interpretation of the matter.

But there is another side of the question directly bearing upon the particular case under notice, and is it fair, one may ask, to either section of the Chrysanthemum as represented by a perfect bloom of that peerless beauty, Mrs. A. Hardy, on the one hand, and a "high-class specimen of Empress of India" on the other, to place them in juxtaposition? I have ventured to give high meed of praise to Mrs. A. Hardy, knowing what it is when in perfection, how difficult it is to obtain, and how seldom such is obtained. Justice should be done to both sections, which that loosely constructed dictum, "the best bloom in the show," does not admit of. Is it fair? Others better qualified to judge, but not more interested, may agree with me that it is not. If so, then what is not fair is unfair, and the sooner this lax method of selecting the best bloom from rival sections the better it will be generally for all concerned, particularly for the judges whose difficulties appear to grow in ratio to the development of high culture.—VESPA.

THE N.C.S. SMOKING CONCERT.

THE gathering for smoking and singing at Anderton's Hotel on Monday night, inaugurated by the Committee of the National Chrysanthemum Society, was a great success. Mr. James H. Veitch acquitted himself admirably in the chair, and the singing and smoking by some 200 ladies and gentlemen were of a high order of merit, not that all sung or all smoked, but only that they were there and happy. It is expected that a sufficiently large sum was realised to place the Society on a firm and independent basis, and that it will soon be capable of holding its shows anywhere where room can be found for them. The cigarettes, speeches, vocalism, and everything else were of the best brands, and though it is thought no profit would be derived by the famous hotel, it is hoped the National Chrysanthemum Society will be greatly strengthened, and that the efforts of the Committee and Secretary to that end will be correspondingly appreciated.—A CHIEF.

NEW FRENCH CHRYSANTHEMUMS OF 1897.

AFTER visiting the Ghent and Paris shows in 1896, where we saw a large number of the new seedlings that flowered last autumn for the first time in England, there was an especial interest in watching their development after cultivation by English growers. As might be expected, Mons. Calvat's novelties formed the bulk of the additions to our already extensive collections, and, as was expected, many of his 1897 varieties seem likely to occupy a foremost position on our show boards in the future, for those who are most interested in the subject from a pecuniary point of view proclaim them to be novelties of the very highest order.

Good as many of them were on the Continent, they seem to have improved in many instances both in size and solidity. A few, perhaps, were not quite so clear and pure in colour, but even then these exceptions are in the minority. The most effective and distinct to my taste are N.C.S. Jubilee, Topaze Orientale, Mdlle. Lucie Faure, Madame Ferlat, Mdlle. Laurence Zédé, Werther, Directeur Liébert, and Soliel d'Octobre among the Calvat race, while it is interesting to note that Mons. Nonin, a Parisian grower, had a fairly large representation among the novelties. A raiser once more generally known, Mons. de Reydellet, distributed some fair novelties that seem likely to please a certain class of cultivators, his best being unquestionably Lucille Mathieu de la Drôme.

After carefully going over my notes I am disposed to think that the undermentioned will be those that suit the taste best of the English exhibitor.

Directeur Liébert (Calvat).—Japanese of large size and compact build. The florets are of medium size, grooved and curly; colour deep lilac mauve.

Lucille Mathieu de la Drôme (Reydellet).—This promises to be a useful addition to the old florists' type of incurved varieties. It is large in size and deeply built; the florets are rather narrow, and regularly incurving; colour pale golden yellow.

Madame Ferlat (Calvat).—A grand massive Japanese incurved of great size and substance. The florets are heavily grooved; the colour pure pearly white.

Mdlle. Laurence Zédé (Calvat).—Another big globular Japanese incurved, with grooved pointed florets of medium width; inside colour violet amaranth, reverse silvery pink.

Princesse de Galles (Calvat).—Japanese with very long florets, which are grooved and of medium width; colour pale pink shaded yellow, tinted purple.

Topaze Orientale (Calvat).—A solid, compact incurving Japanese, very globular and regular in form; florets grooved and broad; colour pale lemon yellow.

Mons. G. Chabanne (Calvat).—A closely built Japanese incurved with rather broad florets; colour rich golden yellow.

Souvenir de Molines (Calvat).—Japanese, close and compact in build; golden carmine bronze, reverse golden.

Leocadie Gentils (Quérier).—A sport from *Enfant des deux Mondes*, raised in France last year. It has narrow grooved florets, the blooms are of large size, and the colour pale pure lemon yellow; very hairy.

Mdlle. Louis Brossillon.—This, too, is a Japanese incurved of very large size. It has medium sized grooved florets that are twisted and intermingly. It is said to be a seedling from Madame Carnot, and its colour is a pure white, very slightly tinted.

Dr. H. Pietro Baragiola (Reydellet).—Japanese with narrow, flat, reflexing florets, not large, but very striking and distinct. The colour is deep golden yellow, shaded rosy carmine.

Madame G. Bruant (Calvat).—A monster Japanese with very long drooping florets; colour pale rose shaded purple towards the tips; centre almost white.

Soleil d'Octobre (Calvat).—A rather early blooming Japanese with medium sized drooping florets, curling at the tips; colour a pretty shade of pale lemon yellow; reverse silvery.

Werther (Calvat).—Globular Japanese of large size, having grooved incurving florets; colour rich deep rosy amaranth, reverse silvery. A fine effective novelty.

Vicomte Roger de Chezelles (Calvat).—Wrongly described in most reports as *Vicomtesse*. A very large Japanese, the centre florets incurving and closely resembling Mr. Briscoe Ironside's seedling *Arona*; colour golden yellow bronze, reverse silvery yellow.

Madame Ph. Rivoire.—This is a Japanese also of great size; florets very broad and ribbed on the reverse; colour pure white.

Mdlle. Lucie Faure (Calvat).—A most superb novelty of the Japanese incurved type. The florets are of great length, good substance, and deeply grooved; one of the purest whites, and will probably rank as one of Calvat's best.

Madame Ed. Roger (Calvat).—Japanese incurved; florets of medium width and grooved, large solid globular shaped blooms. This is a most distinct novelty, being of a pale but decided sea green colour, which, in its early stages, is very effective.

N.C.S. Jubilee (Calvat).—Another very fine globular Japanese incurved variety; the florets are broad and grooved, colour pale lavender pink, with silvery pink reverse. A noteworthy acquisition in its section.

Mons. Massange de Louvrex (Calvat).—Also of the Japanese incurved type; florets of medium width, colour a very fine, clear shade of pale yellow.

Souvenir de Madame F. Rosette (Calvat).—A big solid Japanese incurved, with good florets pointed at the tips; colour plum coloured amaranth, with silvery amaranth reverse.

Mons. Hugnier (Reydellet).—A very large Japanese, but rather flat in build; incurving florets of good substance, and grooved; colour pale rosy mauve, reverse silvery pink.

Papa Villard (Nonin).—Japanese, of good size, but not over-large; the florets are rather broad, curling at the tips; colour very deep rosy mauve, with silvery reverse.

Madame Desblanc (Reydellet).—An incurved Japanese with twisted intermingling grooved florets of medium width; a pretty shade of bright rosy pink.—C. HARMAN PAYNE.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 9TH.

SCIENTIFIC COMMITTEE.—Present—Dr. M. T. Masters (in the chair); Rev. W. Wilks, Mr. Bennett-Poë, Mr. McLachlan, Mr. Veitch, Rev. G. H. Engleheart, Mr. Sutton, Mr. Shea, Mr. Douglas, Mr. Michael, and Rev. Prof. Henslow, Hon. Sec.

EVOLUTION COMMITTEE OF THE ROYAL SOCIETY.—Mr. Bateson called attention to the existence of the Evolution Committee of the Royal Society, the object of which is to promote accurate observations of facts relating to variation, heredity, selection, and other phenomena connected with the evolution of plants and animals. A horticultural sub-committee has been appointed to further the above objects in the hope that any persons engaged in practical horticulture may be willing to assist the Committee by communicating the results obtained, and allowing their operations to be observed and recorded. The Secretary of the Scientific Committee will be glad to receive any communications.

Current Blight.—Mr. Berry gave an interesting account of the history and progress of this destructive injury, especially to Black Currants in Kent. It was first observed some ten years ago, but has now reached alarming dimensions. Miss Ormerod recommended picking off and destroying the buds infested with the mite (*Phytoptus ribis*), the cause of the complaint. This was done, but last year a sudden development occurred, when picking became useless. The "Baldwin," a very heavy cropper, was the variety most seriously attacked. The "Red Budded Naples" were only slightly affected, but this variety is not a heavy cropper, and the fruit being more readily shed, it is not so useful as the Baldwin for market purposes. He suggested that experiments might be carried out at Chiswick to discover which was the most blight-resisting variety, as was done with other plants in Victoria in the Horticultural Gardens, so as to aid the fruit industry in Australia. Mr. McLachlan gave some account of the general habits of the *Phytopti*, remarking that this species was first noticed by Westwood some thirty years ago. It is nearly legless, and lives inside the bud, consequently it is very difficult to reach by means of insecticides. He could only recommend hand picking, unless a mite-proof variety could be found, as they had raised more or less phylloxera-proof Vines. Mr. Michael also contributed further details, observing that all the species of *Phytoptus* were parasites, and that while many species might attack the same plant, a single species might also live on many kinds. They were excessively minute, possessing only two pairs of legs instead of eight, and always protect themselves, so that it becomes a very difficult matter to reach them, as—e.g., in the curled-up edges of leaves, and within buds. It had been found that kerosene emulsion continuously applied by spraying had been more or less effective against *P. pyri*, but acari are far less sensitive to chemicals than insects. The eggs especially have a dense cuticle, so as to render it quite impervious to chemical action of insecticides. The only chance was to repeat the process of spraying, and catch the successive broods. The only thing absolutely fatal to acarid life was boiling water; eggs and all were destroyed at once. Mr. Berry, in replying, observed that the remedy hitherto suggested of cutting down the shoots of the Currant bushes attacked was quite useless. Mr. Veitch suggested that analysis of the branches of the varieties affected or otherwise might reveal some differences, but Mr. Wilks expressed himself as very doubtful of any appreciable differences being attainable even if they exist. Mr. Engleheart raised the question as to whether the Baldwin variety was weaker than others through over-propagation, but Mr. Michael added that *Phytopti* do not by any means prefer weaker plants, but are found more usually on perfectly healthy ones.

Carnations and Caterpillars.—Mr. Douglas exhibited some grubs received from Mr. White, Watlington, Kent, but the species was not readily determinable without being bred to the imago stage. It was suggested that gas lime should be used, as for wireworm, to destroy them.

Pines, Diseased.—Specimens of Scotch Fir and of *Abies Nordmanniana* were received from Mrs. Marshall, Skelwith Fold, Ambleside, the former attacked by the Pine beetle, the latter by *Kermes abietis*. This insect has always proved to be very fatal to this species of *Abies*, and the only

suggestion that could be made was to cut down the tree and burn all parts attacked. With regard to the Pine beetle, to encourage the multiplication of insectivorous birds as far as possible might be advantageous.

Cypripedium with Fungus.—Mr. Douglas exhibited specimens with the roots badly infested by a mycelium. Mr. Veitch at once recognised it as the result of a too damp atmosphere, recording the fact that having on one occasion to make a double roof, it caused so much damp that he lost many Orchids from the same cause, but on improving the atmosphere this completely prevented any recurrence of the fungus.

Primula obconica ♀ × *sinensis* ♂.—Mr. Shea showed a hybrid raised between these species. The flowers were pink, showing the extension of yellow from the throat, with curled petals, and bearing a decided scent of *sinensis*. The calyx, however, was entirely that of *obconica*. The general appearance was nearer that of the female parent. Mr. Shea proposes to re-cross with *sinensis*, and so intensify the features of the male parent.

Two-spotted Arum.—A fine example of this very common condition was received from Mr. Thomas Bennett, The Gardens, Shavington Hall, Market Drayton.

NEW DAHLIAS OF 1897.

NEW Dahlias, like new Chrysanthemums, are now introduced with such rapidity that one is often puzzled to know what to buy. Few Dahlias are bought by the general public the first year of distribution: 5s. and 7s. 6d. being sums above the average Dahlia grower's pocket, so it is usual to wait until the second season, when plants can be procured at 1s. 6d. to 2s. each. This is the price of most of the following, and the varieties mentioned may be considered the best of their class.

Taking the Cactus section first, as it is the most widely grown, I have included some varieties in it that are not in the latest list of Cactus Dahlias issued by the National Dahlia Society, but they may be in it another season: anyhow, their list is only binding at the show held at the Crystal Palace.

CACTUS.

Austin Cannell.—This is of a deep rose colour, with long spiral florets. The height attained is 3 feet.

African.—A deep velvety crimson variety, with the petals rather broad at the base, but well twisted at the ends. This is a fine variety that grows 4 feet high.

Bridesmaid.—The colour of this is pale rose, passing to yellow towards the centre; a lovely flower in a warm season; height 3 feet.

Cedric.—This variety produces long twisted petals of bright magenta colour. It is a splendid Dahlia, but appears to be little known. When well grown it is about 1 yard high.

Cycle.—This excellent variety is of a rich ruby red, paler at the tips. The height is 3½ feet.

Miss Webster.—A pure white true Cactus in a warm climate. The large flowers are borne on strong upright stems. It is admirable for cut flowers or decoration. The plant grows about 4 feet high.

Cinderella.—Dark purple in the centre, the colour of this variety is lighter towards the outside. A very fine floriferous Cactus, but the flowers hang down. Four feet is about the usual height.

Starfish.—A superb variety, with long twisted petals of orange scarlet. It flowers freely on long stout stems, and is probably the best Cactus Dahlia yet introduced. In height it is 4 feet.

Princess Ena.—A delightful combination of amber and reddish orange. The petals are well twisted, and flowers very freely produced on long stems; height, 4 feet.

Ophelia.—In colour this is bright cerise. The petals are long, and it is a splendid flower, the plant growing 3 feet high.

Mrs. Kingsley Foster.—This is a rich golden amber, and must become a great favourite for cut flowers, as it has long stiff stems. The height is 4 feet.

Ensign.—A useful variety, which produces good-shaped flowers of a bright carmine colour. Four feet is about the height.

Iona.—A fine terra cotta hued variety that has twisted petals, flowers freely produced on long stems. This will be a favourite for some years, and is 4 feet high.

Harry Stredwick.—This was sent out to supersede that grand variety, "Matchless," but has hardly succeeded. It is a very good Dahlia, deep maroon, and very free-flowering: the petals are narrower than Matchless.

Fantasy.—Though this is a beautiful flower when cut, it is a failure on the plant, the stems being very short. The colour is bright scarlet, passing to yellow at the base, the petals curling inwards. The plant is 4 feet high.

Aurora.—This is a miniature Cactus of salmon shade, with a bluish tint on the tips of the petals. The plant is most floriferous, and the variety is first-rate for cutting or garden decoration.

SHOW AND FANCY VARIETIES.

Sidney Humphries.—This is of a clear lilac colour. The petals are very good, and the flower is large and bold. It grows 3 feet high.

Queen of Autumn.—The large flowers of this variety are of a new shade of buff. It does not require much thinning, and will be much sought after for exhibition. In height it grows about 3 feet.

Countess.—A blush white, mottled with rosy purple towards the edge. Fine shell petals, high in the centre. It is the best introduction for several years. The height is 4 feet.

Daniel Cornish.—A large terra-cotta red flower, with a good centre. The plant does not require much pruning, and grows about 3 feet high.

Percy Mortimer.—This is a deep claret. It is a good, useful, distinct flower, and grows 3 feet high.

James Martin.—A bright scarlet, similar to the well-known variety W. H. Williams, but blooms earlier. The habit excellent.

POMPONS.

There were not a great many new Pompon varieties sent out last year, but some were very good.

Ganymede.—This is a true Pompon. The colour is fawn shaded with lilac. Nothing has been seen before like this variety in colour. The height is 3 feet.

Adrienne.—The colour of this is a dull red, and the form is good. The plant grows 3 feet high.

Clarissa.—A pale primrose coloured variety tipped with purple. It is fine in petal and outline, and may be termed a lovely Pompon, that is very free-flowering.

Dagmar.—This is crimson maroon, a fine Pompon, and quite distinct; neat in habit, and very free. The height is 2½ feet.

Opal.—Growing to a height of 2½ feet, this is a bright yellow with a white tip.

Dr. Jim.—This is a first-rate Pompon; fine close petal, good centre. The ground colour is white, heavily edged with dark purple; very free.

SINGLE VARIETIES.

Although the single Dahlias are so beautiful, they are giving way before the Cactus section. Three lovely new ones are Trilby, velvety maroon, with white tip; Polly Eccles, fawn, with a red disc; and Naomi Tighe, sulphur yellow, with an orange ring. These have received certificates from the N.D.S., and are all first-rate.—GEORGINA.

CHINESE PRIMROSES AT SWANLEY.

THERE is little room for adding additional honour to Messrs. Cannell and Sons in reference to Chinese Primroses. Ever in the van, growing and showing the finest strains, and well grown too, they have been entitled for years to the highest credit to which florists in relation to any flower may aspire. But grand as blooms of these greenhouse Primroses now are universally, and great the variety in colour of flowers, in character and colour of foliage, and general habit, yet does there seem to have been generally reached such high excellence that it is difficult to move further with these superbly improved strains.

As in other directions the Chinese Primrose is the flower of the immediate season, not only at Swanley but on the breezy hillside of the Eynsford seed farm. At either place the plants are in luxuriant bloom and in splendid form, whether of leaves or flowers, literally by thousands. Out at Eynsford perhaps richer and purer colours and finer forms may be seen, though stocks be identical. That is due to purer air, brighter light, and loftier surroundings at the latter place. To see the plants at either place, and at both especially, is indeed a joy for lovers of the beautiful in flowers just now. Visitors as they pass through, not only the Primrose but all other houses, see no inferior stocks. No matter whether a variety may be represented by fifty plants or 500 plants, all are alike true to character. That is the result of the most careful hybridising of the stock flowers with pollen only of the stock. Of natural fertilisation alone there is little, because insects are absent and the air is still. Aided, however, by the camel's-hair brush Nature does her work of fertilisation perfectly.

The present winter, so far, has been favourable to this operation, and no doubt capital seed crops will result. But breaking away from the giant blooms and traditional types of the *sinensis*, Messrs. Cannell and Sons have already worked what can be well described as a revolution in strains, and their new ones, derived from the now well-known common looking but remarkably free blooming pyramidal White Lady, literally entrance lovers of spring flowers such as Primulas present with their beauty and floriferousness. The intercrossing of the White Lady strain with fine or large flowered varieties has in but a year or two given splendid results. It was only the other day that this said White Lady was rejected at Swanley as rubbish. Mr. Robert Cannell, who controls the Eynsford establishment, on the other hand, saw in it great possibilities, and he raised stock of it, so that, true to the original character, there are white, lilac, and pink flowers with the same dark and finely cut leafage. The section has been termed decorative; not an inapt term, as anyone looking over the houses may see, for the new breaks give relatively fully three times the body of bloom from plants of the same age and dimensions that is furnished by plants of the older strains.

Of course the flowers on the White Lady strain are not large relatively. Those of the original form are smooth edged, much lobed, and rather small. The first break, after crossing with one of the large-flowered whites, gave a selection of still perfectly smooth-edged flowers, much finer and stouter, and quite round, the petals overlapping. This is a great advance on White Lady, and is now in commerce under the designation of *rotundiflora alba*. The tiers of whorls and pyramidal form of the seed parent is in this variety well maintained. There is also a pink or carmine round-flowered form.

Later crosses, using for pollen parents, especially those fine varieties Swanley White and Cannell's White, have resulted in the production of surprising selections having fringed flowers, the very finest of which are *pyramidalis grandiflora striata*, the flowers being here much flaked; *pyramidalis nigrafolia alba*, a fine advance; and finally as the most beautiful of all, *pyramidalis splendens alba*, the flowers of which are large, fringed, perfect in form, pure white, and borne in wonderful profusion. All are singularly floriferous, and give effects that in the bulk are surprisingly beautiful.

In all these strains the heads of bloom are thrown well above the foliage, when in truss form; when, however, the whorls develop, then the heads are indeed striking. As decorative plants for winter and spring use thus easily raised from seed, and grown in such small pots, no other plant can excel them. The development shown in these pyramidal forms so rapidly results largely from the employment as pollen parents of the finest of the large-flowered section; but there should be some limit to it all the same. Directly the large-flowered strain preponderates, and reduces to common form the present striking pyramidal habit, then there will be simple reversion to what is already so abundant that would indeed be a misfortune. The flowers of the most recent cross production are amply large, and of perfect form. When one fails another soon fills the gap; with the large-flowered trusses, big fallen blooms are not readily replaced.

The efforts of breeders should now be rather directed to the securing of other colours, but anything which destroys the elevated character of the florescence should be strictly avoided. But having said so much with respect to the new strain of Chinese Primroses, it is not possible to omit mention of the superb quality and beauty found in the older types. What splendid whites are White Perfection, on dark Fern foliage; Her Majesty, on semi-dark Fern leafage; White Swan, on pale green Fern leaves; and Eynsford White, on curled palmate leafage. There are also others. Flowers of fine form and delicate tint are found on Duchess of Fife, white, just tinted mauve, and some yet small breaks from other crosses have refined tints also. Very beautiful is Pink Queen on green Fern leaves, and the Queen Improved shows on the other distinct advance; but the finest of all the section is Cannell's Pink, really a grand variety, on light green foliage; flowers of great size and of a rich carmine hue.

Emperor is a deep ruddy carmine; and of reds there are Cannell's Red, intense colour; Glow-worm, having a pale ring round the eye, and a bluish shade in the crimson ground; Swanley Giant, even finer and deeper in colour than the preceding; and Kentish Fire brilliant red. The pretty lavender Lilacina, the reddish lilac Mary James, grand purples in diverse shades, magentas, and others, make up indeed a splendid show, to which may be added fine semi-doubles, especially a crimson-hued red, and the well-known Swanley Blue.—A. D.

APPLE LORD HINDLIP.

THIS Apple has been thrice placed before the Fruit Committee of the Royal Horticultural Society, the first time on January 14th, 1896, when an award of merit was unanimously granted; the second time on March 11th, 1897, when it was as unanimously confirmed; and the third time on February 8th, 1898, when a first-class certificate was accorded without a dissentient vote. This at once seems to exemplify the caution of the Fruit Committee, and emphasise the value of a distinct and good late dessert Apple. As will be seen by the illustration, the fruit is above medium size for a dessert Apple. It is broad towards the base, narrowing sharply towards the eye, which is very small and closed. The stalk is slender, and inserted in a deep round cavity, which is lined with russet, the end of the stalk being about level with the base of the fruit. This is yellowish green, covered with broken crimson streaks on the shaded side, these rising from the base, the colour deepening to glossy crimson on the sun side, flecked with russet. The flesh is yellowish, tender, sugary, with a pleasant, though not powerful, aroma. As we have previously said, this is a Rosemary Russet type of Apple. Some of the smoother fruits, however, bear a general resemblance to the American Mother, though much larger. This welcome addition to late dessert Apples was exhibited by Mr. John Watkins of Hereford.

LONDON'S OPEN SPACES.

II.—THE MAKING OF VICTORIA PARK.

VICTORIA Park is one of the largest, most beautiful, and most frequented of the "lungs" of London, and the man to whom London mainly owes its possession of that East End "beauty spot" is not only still living, but labouring as actively as ever in furtherance of Imperial as well as local interests. This is Sir Frederick Young, known and honoured throughout the British Empire as the great apostle of Imperial Federation, and whose special service to London should ever be gratefully remembered. Victoria Park belongs absolutely to the present reign. When Queen Victoria ascended the throne the space was part of a larger area known as "Bonner's Fields." Early in the year 1840 Mr. Joseph Hume (who was so well known in the House of Commons as an uncompromising critic of the estimates in the interests of economy) wrote to Sir Frederick Young's father, the late Mr. George Frederick Young, M.P., calling his attention to the fact that the Government had not long before received the sum of £100,000, the proceeds of the sale of York (now Stafford) House, from the trustees of the late Duke of York; and suggesting that it was a good opportunity for endeavouring to persuade Lord Melbourne's Government to appropriate a portion of the money for the purpose of obtaining "30 acres of open space" as a "playground" for the people of East London. "Certainly," was the reply of Mr. G. F. Young; "but why not try to get 300 acres?" There was no delay in

taking action. On receiving Mr. Hume's letter Mr. Young immediately invited a number of influential friends to meet at his house for the purpose of considering how the object in view could be best attained. It was resolved to have a public meeting of inhabitants of East London, and this took place a few weeks afterwards at the London Tavern, in Bishopsgate Street, under the presidency of the Earl of Glengall. Mr. Young drew up a memorial to the Queen, asking her approval to the scheme, and setting forth sundry cogent reasons in favour of it. This memorial was approved by a provisional Committee; and Sir Frederick Young, as Treasurer and Honorary Secretary of the Committee, got the memorial signed by 30,000 residents in the Tower Hamlets. At that time the "Tower Hamlets" comprised practically the whole of East London, containing about 400,000 inhabitants, who were represented in the House of Commons by two members. That population has since grown to about a million, and thirteen representatives in Parliament.

The memorial was a great success, and made a great impression on the Government. Lord Duncannon, then at the head of the Department of Woods and Forests, was induced to view the scheme so favourably as to promote legislation on the subject. Parliament passed the Bill introduced for the purpose, and the new park received the Queen's name. It was a great triumph of perseverance and devoted effort; and it conferred on East London a boon that increases in value with advancing years.

FIG. 23.—APPLE, LORD HINDLIP.

Mr. Joseph Hume's initiatory letter was written to Mr. George Frederick Young early in 1840; but it was not until March, 1842, that the Bill was introduced into the House of Commons, a change of Government having taken place meanwhile. Just midway between these two dates Mr. Hume, who had apparently not much confidence in officialdom, wrote another characteristic and interesting letter to Mr. Young, as follows:

Bryanston Square, 8th March, 1841.

My dear Sir,—In reference to the application made to the Government from the Tower Hamlets for an open place for recreation, I wish to know whether you have had any answer, or have taken any further steps to forward that very desirable object. Your experience must inform you that unless you persevere and remind, from time to time, public men of their duties, and of the demands made on them, you will find them rather disposed to save themselves the trouble, unless they are to be specially benefited by the object desired to be effected. I do not state this as a reflection on the present Government, but as applicable to all Governments, and hence the necessity of renewing the application. I have effected the purchase of Primrose Hill for the use of the public for ever, a most valuable object; and I have been constant in my advocacy, publicly and privately, since June, 1837. I beg you will do me the favour to let me have a copy of the petition or address to the Crown, with a report of the proceedings at the public meeting, of the presentation, &c., if you have them, that I may see how far I can forward your object. You will learn that I have also got the Regalia in the Tower open to the public at 6d. each, instead of 2s. each, and that we are thus gradually advancing in the right path. Why should the interests of the population of the Tower Hamlets be neglected?

—Yours sincerely,

JOSEPH HUME.

From the above letter it will be seen that the making of Victoria Park and the dedication of Primrose Hill to the use of the public "for ever" were practically contemporaneous. Sir Robert Peel received Victoria Park as a legacy from Lord Melbourne, and there was no unnecessary delay in giving legislative authority for crowning the beneficent labours of Sir Frederick Young and his coadjutors. It was found that the 300 acres, which Mr. George Frederick Young had told his son to try and secure, had not been obtained; "but," said Sir Frederick to a friend who was once talking to him about the struggle, "we did get 298, which satisfied us."

Those who know Victoria Park now can conceive no idea of the squalid, wretched district it was in early times. It was really a township of wretched hovels, popularly known as "Botany Bay" from the fact that it supplied every year a goodly number of unwilling emigrants to the penal settlement of that name. Now it is indeed a pleasure ground worthy the great metropolis. Its avenues, when they attain an ampler growth, will be really superb. It has a lake, or, rather, a succession of lakes, used for bathing and boating, and swarming with waterfowl, while pleasant walks abound, and it is gay with green turf, shrubs, and flowers. One of the lakes is set apart for miniature yacht sailing, and on a summer evening, when a puff of wind is to be had, toy boats and yachts of all rigs and sizes whiten the waters. There is even a yacht club, whose members compete with their tiny craft for various prizes. Cricketing and other sports are freely indulged in on spaces set apart for them, and, according to the last general report of the County Council, facilities for these pleasures are to be increased.

One part of the original plan, however, was never carried out. This was a fine boulevard stretching away from Victoria Park to Limehouse Church. The necessary land could then have been obtained for £5000, but all the available funds had been appropriated for the creation of the park itself. The Commissioners of Woods and Forests approved of the proposed boulevard, and not only had two green lines marked on the map to indicate the site of the road suggested by Sir Frederick Young, but got a clause inserted in the Act of Parliament of the railway company (some time afterwards constructing the Epping Forest line from Fenchurch Street to Woodford) to put ornamental arches to the bridge which would cross this proposed line of road, in order to give a more picturesque appearance to the scene if the project should ever be realised. These ornamental arches still exist, and are, unfortunately, the only relics that remain of the "boulevard" scheme. But Sir Frederick Young has abundant reason to be satisfied with the results actually obtained, and no other man in London has a finer monument to his efforts for the public welfare than he possesses in Victoria Park.—("Lloyd's News.")

THE YOUNG GARDENERS' DOMAIN.

PROPAGATING AND GROWING CROTONS.

Now is a good time to insert Croton cuttings. Healthy well-coloured bits should be selected about 3 inches in length, cut square below a joint, and inserted in thumb pots; only two or three leaves need be taken from the base of the cuttings. The soil may consist of equal parts of fine loam, leaf mould, and peat dust, with a free sprinkling of silver sand. A dash of sand may also be placed on the surface of the soil in the pots, this falling round the cuttings in the process of dibbing them in. I find it desirable when inserting the cuttings to have two or three leaves below the level of the soil. These add greatly to the symmetry of the future plant, and will adhere to it all through the season if the plants are carefully attended to.

Place the cutting pots in a propagating box with a bottom heat of 70°. In about three weeks the cuttings will be rooted, though some may be longer, much depending on the hardness or softness of the different varieties. The young plants may be placed on a shelf near the glass in a low propagating house. In about a week or nine days they will have become accustomed to the exposure, and may be placed singly in 3-inch pots, using a compost of one part fibry loam and peat, half a part leaf mould, and a quarter part silver sand. I think the plants are better without manure at this stage; pot rather firmly, but not hard. The plants may be placed on a shelf as before advised, lightly syringed two or three times on bright days, and kept damp between the pots. Little or no water will be required by the soil until the plants begin to grow. The temperature may be 60° to 65° night, 70° to 75° by day, with a rise of 5° from sun heat.

About the middle of May the 3-inch pots will be filled with roots, and the plants may be transferred into the 5 and 6-inch sizes, according to the strength of the plants, using the same compost as before, but adding a sprinkling of artificial manure, such as Clay's or Thomson's. The plants should be shaded and well syringed until they are growing vigorously, when they may be removed to a larger and lighter house. I think the plants are best in 5 and 6-inch pots the first season, as this is a useful size for table work. If they become root-bound it is advisable to point a little manure into the surface soil; this will keep them going through the rest of the season. If large plants are required those alluded to may be shifted the following spring.

Another batch may be propagated about the middle of June and treated as before, but keeping them in 3-inch pots. These are a very useful size for corner plants in table decoration if grown in fours and sixes of different varieties. Crotons revel in abundance of heat and moisture through the growing season. A sharp look out must be kept for mealy bug and scale. The former may be kept down by looking over all the plants once a week, and touching the bug with a little methylated spirit on a small brush. Scale should be pushed off with a pointed stick, afterwards dipping the plants in a weak solution of softsoap and paraffin or other insecticide.—A LOVER OF THE CRAFT.

FUNGUS PESTS.

ONE of the most familiar fungoid enemies a gardener has to contend with is the Potato disease. That this is brought about by a minute parasitic fungus is now generally recognised. Though it is so small—almost undiscernible with the unaided eye—its work of destruction is none the less rapid. As in the case of mildew, if left unrestrained in its early

attack it is seldom that anything beneficial can be done with it. At all events this is my experience.

This pest attacks the under surface of the leaves, so I think we may learn by this that light, the greatest necessity to the well-being of all green plants, is not essential for the growth and reproduction of this fungus. Were it otherwise the large quantity of haulm and leaves generally produced would act as a kind of preventive. The work and anxiety of the gardener would then be greatly alleviated. But methods and remedies have to be adopted to mitigate (if possible) the voracious attack of this insidious enemy. Unfortunately being so minute, and having such great power of reproduction, it often gains a firm hold before it is detected, which entails greater difficulty, if not impossibility, of eradication. One thing in our favour is, that it has a strong and peculiar scent, and those who know the smell often detect its presence thereby. As soon as the spores are ripe millions of them are wafted by the wind, and brought into contact with more of their favourite prey. Thus I should say the epidemic, as we may term it, travels. Others fall to the ground, and by heavy rain are washed down to the tubers, where they quickly germinate, and cause the well-known disease.

Probably some of the spores remain in the soil, and as they are capable of retaining vitality some length of time, it would be wise not to plant the same piece of ground (should other be at command) with Potatoes twice in succession. When digging Potatoes it is a general practice with some persons to throw the infected tubers back on the surface and leave them. This in my opinion is a bad plan, for in the diseased part there are always a number of spores which might easily get back into the soil, and serve as a stock for future infestations. It would be avoiding a great risk by providing a basket to receive them, so that they may be carried away and burned. I think it quite probable the disease is increased by the decaying tubers accidentally left in the ground, for we find scarcely any decay without one or other kind of fungus being present. We have not far to look for these phenomena if we have a rubbish heap. It seems that as soon as one life departs and its structure and decay commences, other life is brought into existence, and the decaying substances supply food for the sustenance of fungi, when they return to the earth the element that has been taken therefrom. In this sense fungi are valuable servants to mankind.

The remedy I have seen used against the Potato disease was a mixture of bluestone or vitriol (sulphate of copper), 5 lbs., broken very fine and dissolved in boiling water, in a wooden vessel; fresh lime, 5 lbs., dissolved in another vessel, then both thoroughly mixed and strained through a piece of canvas to take out all remaining lumps, and added to 25 gallons of water. This preparation syringed carefully among the haulm certainly hindered the progress of the disease to a large extent.—ASPIRANT.

FRUIT FORCING.

Cucumbers.—Examine the plants in bearing once or twice a week, removing bad leaves and exhausted growths, thinning the shoots, and removing old and deformed fruits. Thin the old growths, so as to admit of training-in young shoots, overcrowding and overcropping being very prejudicial. In securing the shoots to the trellis do not tie them too tightly, but allow room for development. Plants that have been in bearing some time should have the surface soil removed, and previously warmed fresh soil added. Turfy loam, with a fourth of well-decayed manure, will answer, or the turfy loam without an admixture of manure, seeking vigour by rich surface dressings or liquid manure. The bottom heat should not be allowed to fall below 75° or exceed 90°, 80° to 85° being suitable; top heat 65° to 70° at night, 70° to 75° by day, rising to 85° or 90° from sun heat, closing early in the afternoon, damping the pathways on bright mornings and at closing time.

Melons.—The plants in the Melon house may be grown on a ridge of compost the whole length of the house or bed, 2 feet wide at the base, with the top flattened so as to give a depth of 10 to 12 inches, or on hillocks about 2½ feet apart formed similarly, the soil being made rather firm, and when warm the plants may be turned out, firming the compost well, and raising it within half an inch of the seed leaves. The plants may be placed 2½ to 3 feet apart, the primary shoot being taken up without stopping until fully two-thirds the distance they are intended to travel is reached, then pinch out the points of each. When three or four lateral joints are made, the points should be taken out. Some varieties will show fruit on the first laterals, and as early Melons are an all-important consideration, let them remain, taking out the point at the joint above them. To allow all the laterals to remain would very much overcrowd the foliage, therefore rub off every alternate one whilst quite young. After stopping the first laterals, the sub-laterals will show fruit at the second or third joint. The growths should be trained thinly and regularly, so that every part of the trellis is covered evenly with foliage and fruit. The plants will require little water as yet, nevertheless maintain the soil in a moist state, avoiding anything approaching to saturation. Sprinkle the paths in the morning of bright

days, and again at closing time or early in the afternoon. Ventilate carefully, avoiding cold currents of air. When the air is sharp, some hexagon netting or scrim canvas placed over the ventilators will break the force of cutting winds. Maintain a night temperature of 65° to 70°, 5° less in severe weather, 75° by day, raising to 85° or 90° from sun heat, keeping the bottom heat steady at 80°.

Melons in Pits or Frames.—Plants with the growths trained over the surface of the bed being stopped at the second leaf will produce two or more shoots, but two are sufficient, rubbing off the others. Stop the two shoots at two joints of growth; this will give four shoots, taking two to the front and two to the back of the frame. Besides these other shoots may appear near the collar; rub them off whilst quite young, and do not encourage any laterals nearer the stem than 6 inches. This will keep the collar clear. Stop the principal shoots when within a foot of the sides of the frame, and thus throw vigour into the laterals, which will show fruit at the second or third joint; or if not, stop them to induce sub-laterals and a plentiful show for fruit, bearing shoots being stopped one joint beyond the fruit. Cover the lights with double mats at night, and attend to the linings regularly, renewing the old ones as required. Prepare material for making up fresh beds. About a fortnight before it is desired to make up the beds the manure and leaves should be thoroughly incorporated. In a few days it will be seen whether there is sufficient moisture to produce decomposition, fermentation being the result; if not, turn the whole, sprinkling with water so as to moisten the mass, and when in good heat turn again, outside to inside, two or three turnings being required at intervals of a few days to secure sweetened material. The bottom heat of fermenting beds should be 85° to 90°.

Peaches and Nectarines.—*Earliest Forced House.*—This applies to midseason varieties started in December, and to early varieties started a month afterwards. Both will ripen the fruit early in May, but if the very early varieties were set to work early in December the fruit will ripen towards the end of April, or even earlier with sharp forcing, which we do not advise. The trees must be syringed every morning and afternoon to check red spider and other pests. If, however, the weather be dull the syringing must be practised early in the afternoon, so as to allow the trees to become fairly dry before night, or if that does not take place the afternoon syringing should be dispensed with, damping the paths and borders instead, as keeping the trees dripping with water through the night causes weak growth and thin foliage. Outside borders must have protection from the cold, a light mulching of dry partially decayed manure is sufficient. Water inside borders as required, using liquid manure, which will assist the trees in swelling the fruit, especially in the case of weakly trees long subjected to forcing. Vigorous trees will not require any stimulants, excessive vigour being fatal to the fruit satisfactorily passing the stoning period. When the fruits are the size of small marbles thinning may commence, but removing a few only at a time, beginning with those that are badly placed and the least promising. Continue disbudding, taking care to leave a growth at the base of each bearing shoot, and another at the extremity, or at least on a level with the fruit. The shoots retained for attracting the sap to the fruit should be stopped at the second or third leaf, but the basal growths must be trained in to take the place of those now bearing fruit. Shoots upon extensions must be left 12 to 15 inches distance apart to form the bearing wood of the future. It is a great mistake to crowd the trees with growths for which there is not space to allow of full exposure to light and air, therefore avoid overcrowding, seeking to maintain an equal balance of growth throughout the trees, and its solidification by judicious ventilation.

Second Early House.—Let fertilisation still be practised, gently brushing the flowers or distributing the pollen by shaking the trellis, but a camel's-hair brush secures this most efficiently. Admit air freely on all favourable occasions, avoiding, however, cold currents, and provide a little ventilation constantly at the top of the house. Continue the night temperature at 50°, 45° on cold nights, 55° by day artificially, and 60° to 65° from sun heat, not allowing a rise above 65° without a free circulation of air. Syringe the trees when the flowers fade and the fruit is set, moderately, however, at first, so as to assist the trees in casting off the remains of the blossoms. Up to the fruit setting a genial condition of the atmosphere may be secured by damping surfaces other than the trees in the morning and afternoon.

Houses Started in February.—The trees started early in the month are swelling their buds rapidly. Cease syringing when they show colour. Maintain, however, a good moisture by damping the paths and borders two or three times a day, as the weather may dictate, avoiding a close stagnant atmosphere. If the flowers are numerous thin them by rubbing the hand downwards on the under side of the shoots, which will strengthen the remainder. Examine the trees closely, and if there be any aphides fumigate or vaporise with tobacco or nicotine, so as to destroy the pests before the flowers expand. Continue the temperature at 40° to 45° at night and 50° by day, above which ventilate freely. When the flowers expand raise the temperature to 50° at night, 55° by day, and 60° to 65° from sun heat, with free ventilation. On cold nights the temperature may fall to 45° or even less, also 50° by day, allowing a little ventilation constantly at the top of the house.

THE KITCHEN GARDEN.

Garlic and Shallots.—It is only by planting as soon as the ground can be properly prepared that these roots can be grown to perfection. They invariably mature early in the summer. Prepare the ground by digging in a liberal dressing of short decayed manure, and make it fine, firm, and level. The best crops result from planting medium-sized to large, unbroken "bulbs," but if small divisions are planted most of these will

attain to a large or exhibition size, not breaking up. Let the rows be grown 10 inches to 12 inches apart, and plant 6 inches to 8 inches asunder in the rows.

Parsley.—In gardens where it is difficult to obtain good rows of Parsley by sowing now, or later, where the plants are to remain, the plan of raising the requisite number of plants under glass should be adopted. Sow the seeds thinly in either boxes or a bed of soil over a mild hotbed, and do not coddle the plants. When these have formed a strong tap root all may be pricked directly into sheltered borders, arranging the plants 6 inches to 9 inches asunder in rows 1 foot apart. Sink the tap roots to their full depth and fix them well, further protecting from slugs and cold frosty winds.

Parsnips.—One of the effects of the mild winter is the early starting into growth of Parsnips, large quantities of which are undug. It is possible there may yet be a scarcity of green vegetables, and Parsnips will then be in greater demand. The roots ought to be lifted, stored in a heap in a cool shady place, and covered with soil, sand, or ashes. Large Parsnips are of less value than the medium-sized to small roots, hence the breaking away from the old custom of sowing the seed as early in February as the state of the ground permitted. If the open weather continues seeds may be sown now. Especially is this desirable in gardens where the ground ought not to be trampled on if in a somewhat wet condition. If the selected plot of ground was well manured for a preceding surface-rooting crop no manure need be added now. Make the ground as fine as possible to a good depth, and sow the seed thinly in shallow drills 15 inches apart.

Rhubarb.—The crowns of early Rhubarb are on the point of bursting and if any fresh beds or rows are to be formed, this should be done, weather permitting, soon. The finest and most succulent stalks are produced by comparatively young plants, and the poorest from exhausted clumps. Some of the latter should, therefore, be lifted, forced, and destroyed each season, and an equal number of fresh plants be put out. Rhubarb should have heavily manured, double-dug sites, and the stations ought to be 3 feet apart each way. The best early red varieties, with a few clumps of Victoria, meet the requirements of most establishments, and if there is a stock of these, lift some of the older plants, divide into as many pieces as possible—one good crown and a few roots being enough for each division. Replant either singly or in groups of threes, sinking them so that only the crowns show above the ground, fix the soil firmly about the roots, level over, and mulch with strawy manure. Cut out flower stems if these unfortunately appear, but do not draw any stalks for use during the first season. Rhubarb may be forwarded considerably by having heaps of strawy litter banked loosely over the clumps, covering the litter, and adding more occasionally.

Tomatoes.—Young plants with their roots confined in small pots draw up rapidly, especially in dull sunless weather. From these small pots they should be either shifted into 6-inch or planted direct where they are to fruit, doing this before they become badly root-bound. There are various methods of culture open to private gardeners. Excellent crops can be obtained from plants with their roots principally or solely in 10-inch to 12-inch pots, but those who favour this practice must be prepared to apply abundance of water and liquid manure. Boxes a foot or so in depth answer better than pots, because the soil does not dry so quickly as in pots. Pots or boxes can be arranged on front stagings, and the plants trained up the roof, or on pit walls and central stagings, where they may be supported with strong stakes. Tomatoes succeed admirably when planted out 1 foot apart in a narrow ridge of soil arranged along the fronts of houses, but in such positions they must be well looked after, receiving abundance of water and liquid manure, with occasional mulchings. They are also greatly assisted by being allowed to root out from pots, boxes, or ridges of soil into a good thickness of ashes, which should be kept constantly moist with liquid manure. In all cases make the soil firm about the roots, and from the first keep it steadily moist. Tomatoes succeed well in vineries during the first two seasons, but it is a waste of labour trying to fruit them under a heavy canopy of Vine leaves. If, instead of planting them out, the Tomatoes are placed in 11-inch pots arranged across the house midway between the young Vines, allowing them to root out into the border after the fruit has commenced setting, they will produce heavy crops without detriment to the Grape Vines. At this time of year fire heat is necessary for Tomato plants. A night temperature of 55° to 60°, with a rise of 10° in the daytime, suffices, and a little top air should be given during the warmest part of the day.

THE BEE-KEEPER.

HOW TO PROCURE A SURPLUS.

THE chief aim of bee-keepers is to obtain as much honey as possible from their bees. But how this is to be done is a question that should be satisfactorily answered by all who have studied the various systems of bee management and have made the business a success. Others there are who are beginners and are anxious to obtain superior samples of both comb and run honey, but who have their doubt as to which system is the best.

One of the greatest mistakes is to confine the bees in small hives and allow them to swarm during the best part of the honey flow and then expect a surplus. How often one hears of bee-keepers who, after a limited experience with bees in unsuitable hives, or through careless management, fail to obtain a surplus, give up the business in disgust, instead of it proving a remunerative pastime, which it invariably does if worked on the right lines. It is, however, not surprising that such is the case when one takes into consideration the difference of opinion still existing among practical bee-keepers.

For instance, one bee-keeper may advocate large frames of greater length and depth than those favoured by an equally successful apiarist. Both may obtain a large and satisfactory surplus. It does not prove that either is wrong, but may be summed up in one word—management. Therein lies the whole secret of success. It is immaterial to those who pay close attention to their bees and know when extra room is required, and who provide them with it at the right time, whether the hives are large or small. In the former case the space may be restricted by removing all frames not covered by the bees, and in the latter by giving more room. In each instance the surplus will be satisfactory, if that all-important factor, the weather, is favourable. In our recent notes on doubling we fully explained this system of obtaining a surplus of run honey, and also gave the dimensions of the hive, super, and frames most favoured by us, and which are now extensively used throughout this country.

SHALLOW FRAMES FOR SUPERS.

Shallow frames for obtaining a surplus have been much used of late years by advanced bee-keepers. They are of the same length as those used in the body of the hive, but are 3 inches less in depth. They are always placed in the super, directly over the brood nest. The advantage of using shallow frames instead of full sized ones in the super is appreciated by many bee-keepers during an inclement season, when honey is not coming in freely, as bees will often store a surplus (more particularly in this observed early in the season) which would otherwise be lost. If the weather is favourable, and honey is coming in somewhat freely, they require more attention than ordinary frames. There being so much less storage space the frames are filled more rapidly, and if extra room is not provided at the right time, the bees will have the swarming mania, and little surplus will be stored.

When the frames are three parts full they should be lifted bodily off the hive, and a crate of empty frames placed underneath them. The bees will then draw out the foundation, with which they should always be supplied, and will in due course fill them with honey, and at the same time finish off those placed on the top. They should be examined as often as necessary, and when the second crate of frames is three parts full place another crate of empty ones underneath. If the colony is extra strong in bees it may be necessary to place two empty crates on the hive within a few days of each other. We have sometimes had half a dozen crates of shallow frames on a hive at one time, as it is not advisable to remove the frames for extracting until the honey is well ripened, which it usually is when sealed over. There is no place where the honey will keep in such good condition as on the hive.

FULL-SIZED FRAMES FOR SURPLUS.

Although the shallow frame has a slight advantage over the full-sized one, as used in the brood nest, it has the disadvantage of requiring more attention. There is also more labour in extracting, owing to the fact of the frames being smaller. For this reason, and also because the full-sized frame when filled with worker comb is useful for so many purposes. It is not often necessary to place more than one super of nine full-sized frames on a strong stock, if there are some fully drawn out tough old spare combs in stock, as directly the frames are full and about three-parts sealed over they may be lifted out one at a time and the bees brushed off with a feather. But if a carbolie cloth is placed over the top of the frames a few minutes before handling them the majority of the bees will beat a retreat, and the operator will not be interfered with.

The centre combs are always filled first; these may be removed and their places filled with the outside combs that may not be sealed over, the remaining space being filled with empty combs. By

this means the bees are kept constantly at work, and but little swarming will take place. It is necessary to use queen excluder zinc between the brood nest and the super, or the above system will end in failure.—AN ENGLISH BEE-KEEPER.

A WONDERFUL COLONY.

ON page 113 "An English Bee-keeper," referring to what I said about a hive belonging to a member of our Association, which on March 3rd covered nine frames 18 inches by 9 inches deep, and that several drones were observed, and that I said by the 1st of April or the first week in May would crowd the hive. "An English Bee-keeper" says, "I then asked him a question which he has not answered—namely, if according to his own showing a queen would lay from 3000 to 4000 eggs per day, what had become of the bees? On March 3rd the bees covered nine frames, whereas by the first week in May they only covered twelve frames. From the former date to the latter is eight weeks; 3500 eggs laid daily would amount to 196,000. Perhaps 'G. H.' will inform your readers what had become of the bees from this wonderful colony."

The above question implies that "An English Bee-keeper" does not know that in March and April there are many cold days and nights which retard the laying powers of the queen. There are times when the queen lays very few eggs, brought about by the weather, absence of nectar in the flowers, or the little pollen obtained for the wants of the hive. From observation I have proved that egg-laying is governed by the income from the outside.

Then the gales of wind and cold rains destroy thousands of our bees in the early months of the year; too frequently have I had demonstration of this fact. How many bee-keepers have felt a pang when they have seen hundreds of dead and dying bees strewn on the ground around the hives never to rise again, lashed down by the storms? Again, how many bees of this wonderful colony would die of old age from the 3rd of March to the first week of May? "An English Bee-keeper" writes as though I said a queen would lay from 3000 to 4000 eggs in a day in the month of March and the two first weeks in April. Such a thing I never said or thought of. These are the words I used (page 136, February 11th, 1897), "Is a hive with ten standard frames large enough for the requirements of a prolific queen, laying from 3000 to 4000 eggs in the height of the season?"

HOW TO TEST THE LAYING POWERS OF THE QUEEN.

If anyone wishes to prove for himself, put 7 lbs. of bees in a full-combed hive, where a young and vigorous queen (if a hybrid so much the better) has room to lay 3000 to 4000 eggs per day. There are about fifty cells to the inch, both sides of the comb. Let this be done when the weather is fine, with plenty of food in the hive, and a good income from the outside. Measure up on the twentieth day, and if you do not find the above results, your experience will be different from mine. I should like to ask "An E. B." if he has tested the laying powers of a queen, and with what result.

A SUPPOSED MISTAKE.

I went to inspect the wonderful hive referred to in a previous issue by "An E. B.," and, as I expected, it crowded the hive the first week in May. No mistake had been made, the hive had a vigorous queen, and was prosperous in every way. But what has become of the bees? I have explained above what has become of some of them, and the rest entered the supers in good time. "An E. B." told us some time ago they would not do so till the honey flow is nearly over. A mistake was made in my notes last week; instead of reading Mrs. Simmon's hive, it should have read Mr. Simmon's hive.—GEORGE HOWDENSHERE.

* All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8, Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Equal Prizes (Forlorn).—We are obliged by your letter. No good result could ensue by discussing the other matter alluded to so long after the event, and more especially as you say the error has been rectified. No judges are infallible, though some make fewer mistakes than others. We wish you still greater success.

American Productions (Amateur).—You have omitted your name and address. If you supply them, we will give you what information we can; it is not a question suitable for publication.

Pelargonium Stem Killed (T. K.).—The rootstock and stem have been killed by some caustic substance, evidently potash, but there are other substances that give the purple colour. The substance, whatever it may have been, has been poured on the roots, the tissues being destroyed there and for some distance up the stem, while the radiating parts are quite healthy and normal. There is no disease from gall or grub attacks in the specimen.

Zonal Pelargoniums (W. T.).—To afford large trusses with fine petals, young plants are much the best. Sturdy plants of last year's raising from cuttings, and now well established in 4½ or 5-inch pots, if shifted as needed, kept steadily growing, the weaker shoots removed, and the strong retained, produce the best trusses. Pinch the buds off till about six weeks before show time, and then the growths above them, and with judicious feeding after this, large trusses and fine blooms should be forthcoming.

Chemical Manures (A. H.).—We fail to perceive any date of the meeting. In our experience, and it is not short, the effects of artificial manures is largely dependent on the seasons. We have known the money expended on them in dozens of experiments wasted, and guided by these particular experiments alone, which would not be fair, it might be advised that chemicals are of no use. We do not know of any fund being established for providing the sinews of war in what some people regard, though perhaps incorrectly, as a trade propaganda.

Applying Superphosphate to Lawns (F. L.).—Now is the time to apply bone superphosphate to lawns. It is better to add about a fifth part of sulphate of ammonia to the superphosphate, as this quickens its action, or if a light soil, use nitrate of soda instead of the sulphate of ammonia. Three and a half pounds of the mixture suffice per square rod, or if very mossy and but little grass double the quantity may be used. It will brown the lawn, at least it will become so from the dead moss, but the brownness will soon disappear in consequence of the grass growing.

Potatoes for Showing (F. C.).—The best soil for growing Potatoes is a rather light loam, well enriched in the previous autumn with decayed stable or a farmyard manure, and the land again forked over during dry weather in the spring, so as to secure an even blend of the ingredients. Top-dress with either soot (a peck per rod) or rape meal (7 lbs. per rod) just before setting. Choose sets of 2 ozs. to 3 ozs. in weight, reduce the eyes to one or at most two, reserving the strongest, and set during the early part of April, affording the plants ample room. Scattering a handful of superphosphate of lime over a length of 5 or 6 yards of drill when planting is good practice at the setting. Scab may be introduced on the sets, and the best disinfectant is corrosive sublimate (a strong poison), 1 part in 1000 parts of water, steeping the sets for an hour and a half before setting, and not using them for any other purpose but planting.

Pruning Drawn and "Leggy" Rhododendrons (E. Stroud).—The shrubs will now (after two years growth from transplanting) have become well established in the fresh material, and hence likely to push freely and sturdily after being pruned. This is best done during moist and mild weather in April, in such manner as to leave little beyond bare stumps, in order to force the dormant buds into activity at the beginning of summer, and thus secure a good growth with a prospect of its ripening well. The cutting down will do away with all prospect of flowers for the current year, and probably the following season. It appears, however, that you wish to have flowers, as you refer to "cutting down after flowering." This we have frequently done, with the result of securing a feeble growth the first season and no flowers the following year. We have also cut down a portion of the shrubs one season in April, others the next, and so on, until the beds were gone through and the shrubs brought into shape, while there have always been some flowers. Take the course most likely to be in accord with the views and requirements of the proprietor.

Diseased Carnations (E. N.).—The plants are infested with the "fairy-ring spots" of the Carnation fungus (*Heterosporium echinulatum*), first described in England twenty-eight years ago by Rev. M. J. Berkeley, and was introduced from the continent of Europe, thence, in recent years, into North America. The spores are brown in colour, and prickly, as the specific name implies, and when produced in great abundance, as in your case, darken the spot upon the leaf, due to the threads and the spores. The growth of the fungus from the centre of the spot is centrifugal, and the dark colour generally arranged in concentric lines or rings, fancifully representing a miniature fairy ring. The damp of the frame has probably given the fungus a great advantage. The essential conditions of growing healthy Carnations are—foliage free from heavy moisture, and free circulation of air about the plants on all sides. Burn all the plants which are in the condition of those sent to us, as they cannot possibly be cured. Cut off the worst affected parts of the remainder and burn them. Dust the plants with the advertised fungicides containing sulphate of copper, or spray with Bordeaux mixture, so frequently quoted in our columns. Above all give more air; the plants cannot have too much of this, guarding against sharp currents, nor of light.

Names of Plants.—We only undertake to name *species* of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on

which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (W. W.)—1, *Begonia hydrocotylifolia*; 2, *Fuchsia fulgens*; 3, *Pteris cristata albo-lineata*; 4, *P. serrulata*; 5, *Adiantum formosum*; 6, *A. scutum*. (J. C.)—1, *Garrya elliptica*; 2, *Ceanothus rigidus*; 3, *Berberis Darwini*. (W. L.)—1, *Adiantum Collisi*; 2, *A. rubellum*; 3, *A. setulosum*; 4, *Scolopendrium vulgare cristatum*; 5, *Cyrtomium falcatum*. (D. S.)—1, *Spiraea palmata*; 2, *Cypripedium Spicerianum*; 3, a variety of *Dendrobium Wardianum*; 4, *Cypripedium insigne*. (E. R. D.)—1, *Adiantum Pacotti*; 2, *Cypripedium villosum*; 3, *Ficus repens*; 4, *Prunus sinensis flore-pleno*; 5, *Euphorbia splendens*; 6, specimen insufficient, send when in flower.

AN AMERICAN PEST.

WE are all so apt to consider that our own afflictions and troubles are really the worst in the world. Other folk may be similarly afflicted, but in their case we find mitigating circumstances—in ourselves never. If disaster comes it is gigantic—if a blow falls, it is on a raw place.

But after all we may sometimes make a slight mistake; we forget that we are looking at our own and our neighbour's troubles from different standpoints—we see our own through a microscope, magnified in every detail; our friend's troubles through the reversed end of a telescope. In this country we are not often subject to insect invasion; insect life does not assume such vast proportions here as in some countries. True, some years ago Great Britain suffered much from the diamond-backed moth, but if we mistake not, the visitation was only for two seasons, and the ravages were confined to the Turnip crop. This was quite serious enough in all conscience, but still the pest was, as it were, localised. We need not specify certain pests that attack garden produce, that is not our subject to-day, or we might refer to the Onion maggot and the Currant moth, with a host of others.

We have been much interested in an article appearing in a recent number of "Harper's Magazine" headed, "A State in Arms Against a Caterpillar." This caterpillar is known in England, being found plentifully in fenny districts, but is not generally common. We have a specimen of the moth caught in or about the New Forest, Hampshire. The name is *Hypogymna dispar* (the gipsy moth), so called probably from the brown tanned colour of the male, which is always much deeper toned and smaller than the female. On the Continent it is often a real pest, and will strip the whole of the trees in given districts. The caterpillar appears from June to August, then changing into a moth, after a short and busy life of egg-laying, dies.

This pestiferous insect is not indigenous to America. It was brought over to Medford, a suburb of Boston, Massachusetts, about twenty-six years ago by a Frenchman. His idea was to cross this insect with the silkworm, and so produce a hardier type of silk spinner. Unfortunately, however, these creatures got their liberty, and used it, and in 1892 had spread over 220 square miles of territory—a territory bounded by the ocean on the east, Boston on the south, Waltham and Lexington west, and Beverley north. In 1889 they came in such remorseless hordes as to sweep fields, gardens, orchards and trees bare; they not only ate every green thing, but the country literally stank of them, as Egypt did of old in the days of the dead frogs.

Private enterprise did what it could, but when one considers that each gipsy egg cluster contains on an average 600 eggs the work was herculean. A calculation has been made that a pair of gipsy moths could produce sufficient caterpillars in eight years to destroy the entire vegetation of the United States. Not only could they devour all vegetation, but they would pollute all water supplies by their dying hosts. Then the State took the matter in hand, and treated the caterpillar to arsenic spray. To this the tent caterpillar and canker-worm succumb, but not so this new pest. Indeed, it seemed an open question whether the arsenic did not act as a tonic rather than a poison.

Next a plan was tried for catching the male moth. This, in a measure, reduced the fertility of the eggs; but it was only like a child's dam stopping up the course of a stream. Then experiments were tried by extremes of cold and heat, but neither materially affected the creature. A well grown caterpillar will live four days in water, and will subsist nine days without food. The eggs, too, covered as they are with down, seem capable of resisting rain, frost, or fire.

The Board of Agriculture tried the effect of intense flame of vapourised petroleum waste applied by a hose. This had the desired effect, and in the heat the eggs exploded. But eggs are not easily found, or rather they are so carefully hidden in heaps of waste, hollow trees, interstices of stone walls, the under side of branches, the highest twigs that reach the sky, the eaves of houses, the crannies of buildings, that it is well-nigh impossible to reach them all.

Birds have not been found of any material use in diminishing this scourge. Most of the birds will eat a few of the caterpillars or in pupa form, but they do not take to this food with any sort of relish. There is a talk of importing the ring-necked pheasant, as it is believed she feeds her young on this pupæ. One of the schemes tried is

certainly ingenious in its nature. In an infested district it is not an uncommon sight to see whole plantations of trees adorned with a strip of bagging, about 5 feet from the ground. The caterpillar likes the dark, and gladly finds shelter under these strips as the sun touches the tops of the trees. These traps are carefully and systematically searched, and all life killed. In searching suspected ground for eggs sometimes three, or even four, searchers follow one another, so thoroughly is the work done.

Then, again, a system of covering over with pieces of tin and caulking of coal tar is resorted to as a means by which to prevent the depositing of eggs in cavities or wounds in trees. This method also must do something towards the preservation of the wood. Then, too, if trees are badly infested they are burned, as the surest means of stopping the plague.

By all these means carefully carried out the plague has been confined to one district. Were it to cross the boundaries there is no knowing where it might be stayed. The caterpillar is a fatal enemy to the staple crop of the Southern States (we mean cotton), but so far it appears to have a dislike to tobacco.

In Eastern Europe it has been known to defoliate immense regions in a short space, and in Russia only lately its ravages have been most extensive. Unlike other insect pests (save, of course, the locust) it takes every green thing, and leaves the land bare as a desert.

The Board of Agriculture in Massachusetts does not intend to curtail its energies till it has extirpated the caterpillar, and destroyed the last egg. If our Board of Agriculture took similar steps with regard to sheep scab, swine fever, and anthrax, we as a nation would rise up and call the Chairman "blessed."

WORK ON THE HOME FARM.

Though we have had at least two frosty nights during the last week, and one day a slight covering of snow, the weather could hardly be called wintry. But although the general appearances are those of spring, we must remember that February does not belong to the spring quarter, and not shout before we are out of the wood.

The great feature of the present season is its dryness, and the rainfall is still quite insignificant, so that even without a powerful sun and consequent evaporation, we find the land dry enough to work with drag and harrow; so we keep at it, and if nothing hinders there is no reason why the land should not be ready for Turnips this month, if it were Turnip time. We said "if nothing hinders." Alas! The influenza fiend is on the move, and as we write nearly half our hands are down with it. The horses had a threatening but a slight attack, but it soon yielded to remedies. For influenza in horses the best thing is to rest them, keeping the animals warm, rub their throats well with Elisha's embrocation, and give them as much boiled linseed as they can be induced to take.

Though we are getting very forward with the horse work, illness amongst the men, and a scarcity of skilled labour generally, tends rather to accumulate arrears in the manual labour department. Several items of hedging and ditching are still on hand, and though we are prepared to pay a good price to a good workman, they are likely to remain so. When will the youth of the village see that it is to their great interest to become skilled workmen? We have plenty of men (so called), but they are nearly all the wrong sort.

We have not yet got the Wheat harrowed, but hope soon to do so. The early sown Wheat is now very big for the time of year, and the later sown crops look quite well enough.

Turnips are still very plentiful, but those unpied are growing and losing quality very rapidly, perhaps they would pay for storing now. Grass is now much more like May than February, will it be like February in May?

DICKSONS Nurseries, CHESTER

BATH'S NEW SPRING CATALOGUE,
containing description, with full cultural directions, of the choicest CARNATIONS, DAHLIAS, PANSIES, VIOLAS, and many other plants, will be sent post free on application.
R. H. BATH, Ltd., The Floral Farms, WISBECH.

CARNATIONS AND PICOTEEES.—12 choice named for exhibition, 5/-; 12 choice named for border, 5/-; 12 choice named yellow grounds, 6/-; unnamed Carnations for massing, 3/6 per dozen; 20/- per 100. All free for cash. Catalogues post free.—T. LORD, Holbottom, Todmorden.

DUTCH BULBS.—J. J. THOOLEN, Bulb and Plant Grower, OVERVEEN, near HAARLEM, HOLLAND, has the honour to inform that his Illustrated Price List in English, Spring, 1898, is ready, and will be sent free on application. No charges for packing. Orders of 10/- and above entirely free to destinations in England, Scotland, and Ireland, &c. Lowest prices; first quality guaranteed.

100,000 BEGONIA TUBERS.—Large, erect flowering. Single, 12 for 2/3; 100, 16/- Double, 12 for 2/6; 100, 17/- SEND FOR LIST, FREE.—JOHN WELLS, Begonia Nursery, Ryarsh, Malling, Kent.

CELOGYNE CRISTATA, well grown, with bloom spikes, 25 bulbs, 2/-; about 50 bulbs, 3/6; 65 bulbs, 5/-; 100 to 150 bulbs, 7/- to 10/- each. CYPRIPEIDIUM INSIGNE, 2/6 per dozen crowns.—TRUSTEES, late J. STEVENSON, Timperley, Cheshire.

ALPINES, ROCK PLANTS & SHRUBS, and HERBACEOUS PERENNIALS, 2000 to 3000 species and varieties.—Catalogue, 130 pages, descriptive and illustrated, free on application, by postcard, to MANAGER, Guildford Hardy Plant Nursery, Guildford. Prices largely reduced for dozens and hundreds.

IMPORTANT TO MUSHROOM GROWERS.—CUTHBERT'S SPECIALITE MUSHROOM SPAWN. Always alike; most productive. Hundreds of Testimonials. Per Bushel, 5/-.—R. & G. CUTHBERT, Seed, Bulb, and Plant Merchants, Southgate, N. Established 1797.

HEATING APPARATUS.—Medals 1875 and 1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2/6; post free, 2/10.—JONES and ATTWOOD, Stourbridge.

ALL WHO WISH GRAND RESULTS should use THOMSON'S IMPROVED VINE, PLANT and VEGETABLE MANURE. This Valuable Manure is yearly growing in public favour. Can be had of all Nursery and Seedsmen, or direct from the makers, WM. THOMSON and SONS, Ltd., Tweed Vineyard, Clovenfords, Galashiels, N.B. Price Lists and Testimonials on Application. 1 cwt. and upwards Carriage Paid to all stations in Britain and Ireland. London Agent—Mr. J. GEORGE, 14, Redgrave Road, Putney. Agent for Channel Islands—Mr. J. H. PARSONS, Market Place, Guernsey. Also THOMSON'S SPECIAL CHRYSANTHEMUM MANURE. ½ cwt. Carriage Paid to all stations in Britain and Ireland.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd., Leeds.**

GREENHOUSES from £2 8/-, VINERIES, CONSERVATORIES, well-made FRAMES, painted or glazed, from 21/-. Illustrated Price Lists free. MAKER TO H.M. THE QUEEN and H.R.H. THE PRINCE OF WALES.

POTTER, HAWTHORN & CO., Manufacturers, LONDON WORKS, READING. (Name Paper.)

Journal of Horticulture.

THURSDAY, FEBRUARY 24, 1898.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

CARNATIONS.

NAMES AND KINDS.

WHERE the cultivated Carnation originated, whence and when it was introduced into England, are interesting items in its history which unfortunately have never been elucidated. In the sixteenth century it seems already to have possessed a European reputation and to have been cultivated with great care. Previous to this, however, its history is practically a blank, and it comes suddenly within our ken an established garden flower, the finest varieties of which were cultivated in pots and protected during the winter months in frost-proof places. In England the earliest mention of the flower, a single kind, was made previous to 1420 by James I. of Scotland in the well-known "King's Quhair," the designations employed being respectively "Red jeraffleris" and "gerafloure." Some have supposed that Chaucer by "Clowe-gilofré" referred to a Carnation, but in both the instances it is mentioned by that poet it is in connection with other spices, such as nutmegs, liquorice, "Cetewale of Prys," an expensive kind of Spikenard, supposed to be a Valerian; ginger, grains of paradise and cinnamon. The passage describing these as growing together in the Garden of Myrthe is a poetic fiction, and we know it could not occur in fact.

The earliest names applied to the Carnation in England may therefore be safely concluded to be "jeraffleris" and "gerafloure," the former being used a century later in Gawain Douglas' Virgil's "Enid." Giroffier seems identical, and they appear to be contracted rather than corrupted forms of Caryophylleus. But although we conclude Chaucer's Clowe gilofré to be the same with the Cloue Gylofres seen by Sir John Maundeville growing in the Spice Islands, and therefore the Clove Spice, there is no reason to doubt that the designation in course of time came to be applied to a Carnation possessed of a pronounced scent of cloves.

The simple Gillyflower, which was spelled in a great variety of ways—Gyllofyr, Gillofer, Gillyvor, Gelloflore, Jillyflore, and Jellyflower being a few

examples—has been referred to a like origin. But we cannot forget that this word was an appellative which included several distinct flowers. Wallflowers, for instance, being called Wall-, Yellow-, and Winter-gillyflowers; the common Stock, White- and Stock-gillyflowers; *Hesperis matronalis*- Queen- and English-gillyflowers; and the white and red Campions, Wild Gillyflowers.

I have sometimes thought that "Gillyflower" may have, indeed originated as a name descriptive of those flowers which were worn on all occasions of festivity by young women, the common name of whom was "Gill," in the same way as the young men of the same class of society were known by the soubriquet of "Jack." Sir Walter Scott mentions as curious an old belief that Gillyflowers were planted around the gates of Paradise. In this connection the word may not refer to the flower at all, nor in the old ballad of "Clerk Saunders," where May Margaret is assured concerning certain women that

Their beds are made in the heavens high,
Down at the feet of our good Lord's knee.
Well set about wi' Gillyflowers,
I wot, good company for to see.

"July flowers" is a designation as applied to Carnations about which there is no difficulty. It was first used by William Lawson in "The COUNTRY Housewife's Garden" (1618). He says, "I call them so (July flowers) because they flower in July." "Sops-in-wine" is a somewhat older name than the last. It appears to have been used first of all as one of the many names borne by *Medicago sativa*. But we know from the Glosse to Spenser's "Shepherd's Kalender" that it was also "a flower much like to a Coronation, but differing in smell and quantity." In 1581, a year or so later than Spenser's Pastoral, it appears along with "Jillyfloures Coronations" and other flowers in Lillie's "Euphues and his England."

It has been thought that the name arose from the flowers having been employed as flavouring agents in wine and beer. Stevens, however, in a note to Shakespeare affirms that it "borrowed its name" from a long-forgotten custom that followed closely the conclusion of the marriage ceremony. This was the drinking by the bride and bridegroom from a bowl consecrated wine and wafers to which the very old name of "Sops-in-wine" was given. "Sops-in-wine" again as a flower was "worne of paramours." It seems to have been the same single form as that mentioned in "The King's Quhair," and to have had some meaning as a token between lovers. Not crowned till later, "King" James looked upon the flowers sent him by the Princess in that light, and it has no doubt some connection unreported to us with the "contracting cup" of the marriage ceremony.

This name appears to have been superseded by "Clove Gillyflower," the single variety. Both this and its double form continued for generations a favourite flower with Englishmen of all classes. The double form is portrayed in Hill's "Eden" (1757), and is a variety with few petals, rough, and with edges deeply serrated. Single and double are both mentioned in 1789 by Abercromby; but in 1820 Hogg declares them to be lost to gardens.

The single Clove Gillyflower was the type employed for the few economic purposes to which the Carnation was put. These included a syrup and a conserve of the flowers which Culpepper informs us were good "against the plague." Evelyn mentions the use of Clove Gillyflower in vinegar, and by the name of Clove Gillyflower water a cordial was prepared of brandy, water, and sugar, in which the flowers of the single red Clove had been steeped. This was in much repute in the eighteenth century, and "Ratafia d'Eillets" of the French, in which the petals of the single Grenadin Carnation are used, seems much like the above. In "Country Contentments" (1623) a curious method of pickling the petals in sugar and vinegar is described, and how the flowers were used with Purslane and pickled Cucumbers in forming flowers laid on flat dishes. We are informed that "These Sallets are both for shew and use, for they are more excellent for taste than to look on."

"Pink," though now employed to indicate only the flower which we know by that name, at one time was applied to several distinct

plants. It was also one of the names of the Carnation. An instance occurs in a children's coloured picture book (printed in "lively" colours) of the early years of the seventeenth century, in which by the name of "Jagged Pink," a crimson Carnation of a fair size and very double, is portrayed. This may have been the old "Clove Pink," which was red and quite distinct from the plant known by that name to-day. This, and the Old Man's Head Pink, were by some authorities considered true Carnations.

The last designation—Carnation—is the best known of all. Some little difference of opinion has existed as to the derivation and meaning of this word. Hogg, as an instance, having discovered that it meant from "Carnation" a "flesh coloured" flower; and it was "coronarium" from its having been used for chaplets and garlands for the head." The first derivation is unsupported by any evidence. "Coronaria," on the other hand, is a name beyond dispute. Dodœens declares that some have surnamed it "altilem coronarium," cultivated, or perhaps double coronaria, and the reason why it was so surnamed was because of its employment in garlands (coronis) and particularly "the double," which was used "almost beyond measure."

Carnation, as a name, was at first by no means popular, and perhaps it is only of late years it has become truly so. Anyhow, while Spenser and Lillie name the Carnation along with Gillyflowers—the last of which, in these instances, must refer to another plant—most writers leave the novel designation severely alone. Gerarde eschews it, though it is admitted his Herbal is largely a translation of Dodœen's "History of Plants"; while Lyte, on the other hand, has it in a translation of an earlier work of the same author. Bacon refers to Carnations as "gillifers of all kinds." Lawson seems to have been quite unacquainted with the word, though he grew nine or ten varieties of July flowers as large as Damask Roses. Neither Surfleet nor Markham name it, though Peacham, writing about the same time, mentions "Cloue gilliflowers and Carnations." In 1664, Evelyn distinguishes between Carnations and Gilliflowers; but Lawrence (1726) says Carnations are also called "Gillyflowers or July flowers." From about 1700 "Carnation" was used by florists, and Gillyflowers continued for long the everyday pretty name in common use.—R. P. BROTHERSTON.

(To be continued.)

SIMILARITY OF LIFE IN THE VEGETABLE AND ANIMAL KINGDOMS.

(Concluded from page 105.)

REPRODUCTION.

So anxious seems the beneficent mother—Nature—to preserve the varied forms of life that, at first sight, the power implanted in her subjects of the vegetable kingdom is so great, and the desire in the other kingdom so assertive, to "multiply and replenish" as would warrant the conclusion that it is considerably overdone. She has, too, her own methods of balancing matters in this marvellous fecundity of life, as may be noted by race living at the expense of race; in the multitudinous examples illustrating the interdependence of species chiefly, but not wholly, in the animal kingdom; and the highest stage of interdependence between the two great kingdoms. The wonderful methods employed as a substitute for that missing link, volition, in plant life whereby insects are the winged messengers of love in the silent kingdom with other ways and means to the end of fertilisation and reproduction, cannot but excite our wonder and admiration. So the great plant-world lures by a thousand charms of fragrance, of colour, of nutriment, or some essential to the economy of animal life, the subjects of it to supply the deficiency to their mutual advantage.

It is not felt to be necessary to enter at any length into details which are so easily to be acquired from botanical treatises. Like begets like, as a general rule, until man or other agent intervene. Certain safeguards, too, protect the rights of Nature from being unduly tampered with. In the matter of hybrids, whether the barrier on which is inscribed "Thus far shalt thou go and no farther," wisely intervenes where confusion might commence, and the ending be in dire disaster. Traversing the whole range of life in both kingdoms pretty much the same means to the same end of perpetuation of species are frequently in evidence. Dr. Lindley speaks of trees arriving at the age of puberty, and says respecting it, "This alteration of habit . . . by the influence of which the sap or blood of the plant is to be partially directed from its former courses into channels in which its force is to be applied to the production of new individuals rather

than to the extension of itself." A very common simile recognised by earlier students of nature was that pertaining to seeds of plants and eggs of animals, including the reptilia and fishes, as well as of birds. One great difference undoubtedly obtains in the generally accepted dictum, that the seed can only be formed subsequently to the action of fertilisation, whereas egg production is not dependent upon that.

One can hardly touch upon such phases of our subject without being tempted to inquire further into matters so fascinating, yet a little aside, perhaps, of our present purpose. In allusion, however, to that interdependence previously noticed, we have, I think, in parasitic life another phase of similarity not to be overlooked. Apart from all considerations of insect life infesting plants, partly or wholly dependent upon them at some stage of their existence, there are those parasitic vegetables, including fungoid organisms, which to their hosts are the detrimentals of society. Here we have great robbers and little rogues of more insidious habits, which in their independence and manners of living are very similar to that unenviable state of life among certain of the insectivora revealed by the magnifying lens, and described as follows:—

"Big fleas have little fleas upon their backs to bite 'em,
And little fleas have lesser fleas, and so *ad infinitum*."

But it is scarcely necessary to go farther, possible though it is to bring forward a vast mass of evidence in support of that similarity existing between the two great kingdoms of life.

We are, as I said, apt to place in juxtaposition the highest forms of animal life, and see nothing but a great barrier, so dismissing the matter as of no utility to practical workers in the great field of Nature. Whereas, the farther we look, and the more profoundly we investigate, that barrier dwindles away into dim prospective, to the very germ of life itself; to where, indeed, arises the great barrier, the veil of creation, which mortal vision may not penetrate. 'Tis given us, however,

"To trace in Nature's most minute design,
The signature and stamp of power divine."

And we can hardly do so, I think, without mutual advantage to ourselves and the labour we love. Extended as our powers may be, and great as is the power bestowed "to have dominion," the greatest wielders of it in the field of science have utterly failed when attempting to measure the infinite by the finite of human understanding. They have told us that life cannot exist upon certain planets because certain conditions, regarded as essential to it, are absent; just as a superficial reasoning says there can be no relationship between the two kingdoms of life, whose very existence is interdependent. From the former notion we can hardly hope to escape, being of the earth earthy; but as students of Nature it is given us to take occasion by the hand, and make the bounds of freedom wider yet.

In conclusion, one fact remains to be faced in the pre-supposed question I have to answer—viz., What practical ends are served by bringing this subject before men who are so essentially practical? Emerson speaks so pointedly in answer to this that he is all-sufficient to act as deputy, expressing clearly what is felt to be the truth of the whole matter. He says, "All our science lacks a human side. . . . Buds and stamens, and spores, on which we lavish so many years, are not finalities; and man, when his powers unfold in order, will take Nature along with him, and emit light into all her recesses." Then, and then only, I venture to add, shall we attain to the highest results; then will the triumph of mind over matter be complete.—INVICTA.

THE BLACK CURRANT.

(Concluded from page 96.)

ONE point in connection with the variations in the Black Currant is worth attention, and that is in regard to raising them from seed. By careful and continued selection a greatly improved race of varieties could be obtained; and some, perhaps, that would be less liable to the attacks of the most troublesome pest—the bud-mite. The seedlings are exceptionally vigorous, in three years are large enough for transplanting, and will produce sufficient fruit to determine their merits. The seeds can be raised in pots in a cool house or frame, or they may be sown out of doors, but the former method is preferable.

A few words will suffice respecting cultivation, for almost any fertile soil that is not too dry suits the Black Currant, and they will thrive in much wetter situations than Gooseberries or Red Currants. To insure the best results they require liberal treatment as regards manures, and I have found nothing better than a dressing of well decomposed farmyard manure, and a sprinkling of superphosphate of lime and kainit, the first at the rate of 20 tons to the acre, the chemical manures at 3 cwt. and 2 cwt. respectively in the order named. It is quite as essential to avoid digging close to Black Currants as it is with Raspberries, for the roots extend a considerable distance and often near the surface. I have found vigorous roots two years after

planting radiating 3 feet from the stem, thus covering an area 6 feet in diameter for each bush. The addition of the chemical manures I have found to have a beneficial effect even in smaller quantities than those named, and applied in alternate years.

The great recommendation of the Black Currant has been its freedom from diseases and insect enemies, but its value has been lessened in these respects greatly within recent years. First, there is the tendency to the loss of large branches quite suddenly, sometimes nearly half a bush dying in this way; and this has been generally attributed to impoverishment of the soil, to which cause it is, perhaps, partly due. But there is another cause, and that is traceable to the pruning, for close examination has shown in almost every case which has come under my observation that the dead portion of the stem was in direct communication with a cut branch which had died back, and either the decay has extended from this into one of the main stems or a fungus has helped in the mischief. It often happens that the whole bush has made vigorous growth, and there is nothing to indicate there is anything wrong until the season of growth arrives in the spring, when the buds half expand and wither. As far as I have observed, the evil is avoided to some extent by cutting old branches clean out, as the older wood does not heal readily, and in other cases cutting close to a good bud on younger wood when the bush is being formed.

But there is a greater evil attending the Black Currant than that described, and it is one of which the serious nature has not been generally recognised, though the mischief is extending so rapidly that unless some efficient means of checking it is promptly discovered it will destroy the whole trade in this fruit. I allude to the Currant bud mite, which causes the swollen buds, too readily detected in hundreds of plantations at the present time, and which has been repeatedly described and illustrated in periodicals and books, but without any preventives or effectual remedies being recorded.

The first notice of this pest known to me occurs in the *Journal of Horticulture* correspondence pages in January, 1867, where inquiries are answered referring to its appearing in the neighbourhood of Glasgow and other parts of Scotland. Two years after this the Rev. J. M. Berkeley had specimens sent to him, and the injury was determined to be due to the presence of a mite, a species of *Phytoptus*, afterwards described by Professor Westwood as *Phytoptus ribis*. But there seems to be some variability in these minute pests which has occasioned much discussion as to their true nature. The practical aspect of the matter is that these pests attack the young buds in their earliest stages, certainly the effects are visible in October and November, they feed on the inner scales of the bud, set up an abnormal condition resulting in a swelling of the tissue until a large globular bud is formed, and in the spring these do not open but wither. At first a few affected buds only may be observed, and this is the time to adopt remedial measures, the first means being the careful removal of every swollen bud, placing them in some vessel for burning. Then if the bushes are thoroughly and repeatedly dressed with some approved and penetrating insecticide the damage may be checked for a time. But I have never yet seen a plantation completely cleared by any other method than cutting the bushes down close to the ground, dressing the stumps, and watering the soil with a liquid insecticide, or giving a dressing of lime, afterwards stimulating the plants to vigorous growth by heavy dressings of manure.

When once the mite has a firm hold, the total destruction of the bushes, and the occupation of the ground with another crop for a year or two, seems to be the only means of dealing with it. I have seen bushes with from 100 to 300 diseased buds, and the enormous number of mites present can be imagined when it is remembered that they measure about the 200th part of an inch in length, and every bud contains swarms of them. As to the time when the bushes should be dealt with, I would suggest spraying before the buds expand and immediately after the fruit is gathered, for it appears that the increase of the pest takes place from February onwards through the summer months. Miss Ormerod gives, in her "Manual of Injurious Insects," full details of what has been tried, but the Board of Agriculture has also issued a leaflet which can be had free on application to the Secretary, 4, Whitehall Place, London.

The various mixtures that have been tried, and recommended for application in spring and late summer, are the following:—4 gallons of petroleum and 6 lbs. softsoap to 150 gallons of water; 2 gallons carbolic acid and 6 lbs. softsoap to 100 gallons of water; 2 lbs. sulphur and 3 lbs. lime boiled in 3 gallons of water, and the plants syringed with a dilution at the rate of 3 pints to a large pail of water; and 4 ozs. sulphuret of lime and 2 ozs. softsoap to a gallon of hot water. The effects are varied and uncertain. The difficulty, obviously, is to find something that will penetrate into the buds and destroy the mite without injuring the bush, and the mixtures or compounds of sulphur seem to afford the best chance of doing this, especially if they can be applied in a form that will adhere to the buds. The matter is, however, so important that some organised system of dealing with the pest should be decided upon generally.—FRUIT GROWER.

EARLY CABBAGES.

CROPS grow apace during the continuance of the mild weather for which this winter has been remarkable. On all sides we see evidences of the forward state of vegetation; even the Thorn hedges are bursting into leaf, and gardening operations are being pushed on with all possible speed. I do not remember having previously seen autumn-planted Cabbage in so forward a state as they are now; in fact I saw an amateur who possesses a warm sheltered garden cutting nice heads of Ellam's Early a fortnight ago. Such heads are, no doubt, useful even at this season, but they do not possess the delicate flavour and crispness for which young Cabbage are noted during April and May, neither is it desirable to have them ready for cutting thus early, because there are plenty of seasonable Kales and other Winter Greens ready for use, and as the frosts have been so slight Broccoli have for once given an almost continuous supply where successional varieties have been planted.

Most good cultivators are too cautious to place "all their eggs in one basket," and they act upon the same principle in regard to Cabbages, by raising early and late plants in late summer or autumn. The latest will this year prove invaluable, as they will afford good heads for cutting at a seasonable time when premature crops are over. If such young plants are still in temporary beds where they were pricked out in the autumn no time should be lost in planting them in their permanent quarters. Rich ground should be selected for them, as it does not pay to grow Cabbages in poor soil, for the progress made under such conditions is too slow, and the heads lack the essential tenderness and fine colour when ready to cut. Heavy land which was dug and thoroughly manured in November or December will during a fine day be in the right condition to be worked with a Canterbury hoe, which is an excellent implement for reducing lumps to a finer state and for stirring the whole without reducing the soil to such a fine condition as to cause it to become hard, close, and impervious to air. There is no necessity to draw drills for planting in when the soil is stiff, indeed it would often be a troublesome business to do so in early spring, and there would be no compensating results.

For early varieties, if the rows are arranged 18 inches apart, and the plants set 15 inches asunder in the rows, the space allowed will be found ample, as we possess several good types of Cabbages whose leaves do not spread greatly, and the hearts are conical rather than round. When the planting is done on light soils, the digging may with advantage be left till planting time, when, of course, a heavy coating of manure ought to be given. I find light and old garden soils are often teeming with grubs, which make short work of young plants. The remedy at the time is, of course, to dig up the stumps left, catch and kill the depredator, and dust freely with slaked lime, but steps ought to have been previously taken to destroy such pests by spreading gas lime upon the land in the autumn, or at least three weeks before it is dug, 30 lbs to a rod being a suitable quantity to apply in the latter case, but in autumn 50 lbs. may be safely used.

The usual garden plan of lifting with balls of earth and planting carefully is one that should be always persevered in, as plants so treated grow away without receiving a perceptible check, and in the case of early crops a gain of time means a proportionate gain of money in the shape of better prices. It is encouraging to find that cottagers and allotment holders are in many instances now turning their attention to this important detail, yet there are still far too many who pull up their plants ruthlessly, and then thrust them far too deeply into the soil, the result being slow progress in many cases, decay at the roots, or clubbing in others.

As all autumn-raised plants are likely to this year be earlier than usual, a sowing should now be made to afford good heads in June and July, a time when Cabbages are by no means to be despised, especially when large demands for the servants' hall have to be satisfied. Good varieties to sow are Dickson's First and Best, Sutton's Earliest, Ellam's Early, and Veitch's Earliest of All. I have grown these sorts repeatedly, and although Ellam's Early is the best for autumn sowing, either of the other varieties named heart slightly quicker when sown in spring than the old standard variety. When growth is well advanced frequent stirring of the soil with a hoe should be the order of the day, especially during bright weather. At showery times a little nitrate of soda scattered along the rows will give great impetus to growth, and should the weather prove dry, manure water applied copiously will quickly show its effects in the shape of glossy vigorous leaves. Under all these favourable conditions the plants seem to grow by leaps and bounds, and the cultivator feels he is getting due return for his labour, for be it noted that the reward of the gardener is not received in this world's goods alone, but also in the instinctive sense of satisfaction which is awakened in the human breast when vegetation is developing luxurious growth. Even the Cabbage grower has his happy moments; who has not?—H. D.

LÆLIA ANCEPS WADDONENSIS.

THE dull period of the year at the Drill Hall has, this season, been wonderfully brightened by the many superb Lælias that have been exhibited by different growers at the several meetings. More than one of the varieties have received recognition at the hands of the Orchid Committee, and in every case the honour has been thoroughly deserved. The latest to receive a first class certificate was Lælia anceps waddonensis, staged by Phillip Crowley, Esq., Waddon House, Croydon, the Chairman of the Fruit and Vegetable Committee of the R.H.S. A glance at the woodcut (fig. 24) will suffice to show the splendid shape of this charming variety of anceps, which, save for a blotch of yellow and purplish veins in the throat, is pure white. From tip to tip of the petals the measurement was $4\frac{1}{2}$ inches, with a depth of half an inch less. It is a lovely variety, and, needless to say, was much admired.

ORCHID APPLIANCES.

WE have received particulars of several of the West's patent specialities for orchidists. The baskets are now no novelty, and have found favour with many well-known Orchid experts, as quoted in the circular. Their chief merit appears to us to be in the level top and fixed bottom, the former rendering the plant more easily fixed in position, the latter preventing the basket from twisting out of shape and so snapping the roots. They are offered in various shapes and sizes, some made to hang against a wall, others in the shape of a pot, and a very useful contrivance for dwarf-growing Orchids of the Sophronitis class or small Lælias will be found in the patent raft. There can be no risk in purchasing these patent baskets, as they are sold at as low a price as the ordinary style. By the courtesy of the makers we are enabled to give illustrations of the West's patent pot rim (see figs. 27 and 28, page 177). This serves a double purpose. The rim may be placed in any class of pot, and not being bevelled so sharply as the pots, makes a chamber all round the inside to catch any surplus water, this being carried through the holes to the compost. The holes being made in the form of an inverted triangle the water drains away very slowly, so whatever part of the chamber it falls into it is bound to find its way to most, if not all, of the holes, and therefrom to various parts of the compost. It may also be used to stand Orchid pots on, and is a great deal better than the usual inverted pot, as air reaches the bottom of the pot through the pierced sides. Full directions for its use in one or two other ways are given by the maker.

The West's patent ivory labels are excellent in every way—neat, inexpensive, and quite harmless to the plants, which many are not. The ordinary wood label is a great nuisance in Orchid houses, always rotting, and when made of some kind of wood always covered with a troublesome fungus. They are apt to damage the roots when placed in the pots, and are quite unsuitable for baskets; but the small copper wire shank to these is harmless and takes up no room, while it may easily be attached to pots, baskets, or even blocks.

THE QUEST FOR RARE ORCHIDS.

ASHWORTH V. WELLS. — This was the defendant's appeal before Lords Justices A. L. Smith, Chitty, and Collins, by which he sought to prevent a new trial of the action, as ordered by a Divisional Court after judgment had been entered for him in the Manchester County Court.

The action by which plaintiff sought to recover £50, was a very interesting one, relating to the culture of Orchids. Mr. Wells, the defendant, was the owner of an extremely valuable collection of Orchids, which in 1895 he offered for sale by auction in London. The plaintiff, Mr. Ashworth, who was also a well known Orchid grower, possessing a collection valued at between £15,000 and £20,000, attended the sale and purchased one of the lots, which was described in the catalogue as a "Cattleya Aclandiae alba, seven bulbs, three leaves—the only known plant." A white variety of Cattleya Aclandiae is perfectly unique—no lover of Orchids has ever been fortunate enough to find one—and this specimen was knocked down to plaintiff for 20 guineas. He placed it among his other Orchids and carefully nurtured it for two years, and when at the end of that period it blossomed, its flower was not white, but purple.

Having thus demonstrated itself not to have been an alba, but a rather common Cattleya Aclandiae, the value of which would not be more than 10s., the plaintiff sought to recover his 20 guineas, and also special damages for false warranty; and he limited his claim to £50, so that the County Court might have jurisdiction. It was not disputed that the description in the catalogue amounted to a warranty of

the Orchid as being an "alba," but a question argued was whether the disappointed plaintiff could be entitled to special damages on account of that warranty having proved false, or should merely receive back his 20 guineas, plus a small sum for his loss of time and for trouble during the two years of useless cultivation. The County Court Judge took the latter view, and held that plaintiff was entitled to 20 guineas, and £2 compensation; and as defendant had paid those sums into Court, judgment was for him.

On plaintiff appealing to a Divisional Court, their Lordships decided that the County Court Judge ought not to have restricted the damages to the sum actually paid, but ought to have taken into account the value which the Orchid would have reached on declaring itself a white *Cattleya Aelandiæ*. They sent the case back to have the damages assessed on the wider basis upon a re-trial. Against that order defendant appealed.

Having heard counsel on both sides, Lord Justice Smith, in the course of a long judgment, said the warranty was that this plant when it bloomed—if, in fact, it ever did bloom—would produce a white blossom. It was not a warranty that the plant would blossom, or even that it would live. The plaintiff bought it knowing that he would have to keep it a considerable time, in the ordinary course of events, before there would be a flower. It was not suggested that if the cultivation had been different the plant would have produced a white instead of a purple flower. The County Court Judge was wrong in deciding that Mr. Ashworth was only entitled to have his money back, and was not entitled to claim anything more by way of special damages. Evidence was given to show that a white *Cattleya Aelandiæ*, if one was ever found to exist, would be worth at least £50. The Court would order judgment to be entered for plaintiff for £50 with costs, and the defendant's appeal would be disallowed. Lord Justice Chitty and Lord Justice Collins substantially agreed. The appeal was accordingly dismissed.—("Daily Mail.")

DENDROBIUM BRYMERIANUM.

THIS is certainly one of the most interesting *Dendrobiums* in flower at this season, and one of the showiest if well grown and flowered. The stems are fusiform, upwards of 18 inches in length, and the flowers appear in small racemes of two or three, chiefly about the upper nodes. These are about 3 inches across, the sepals and petals of the usual form, as seen in the genus, but instead of the usual lip this segment is cut up into many fine filaments, forming a bright golden yellow fringe about an inch in depth. The species is strictly evergreen, but, as will be noted, requires a mode of treatment more resembling that of the deciduous section.

It is easily and freely propagated by taking off and either potting singly or massing the young growing shoots that usually appear in planting about the upper parts of the stems or pseudo-bulbs. The safest time to remove them is after they are finished growing, but before they commence a second season. If potted singly they must not be placed in pots larger than the 3-inch size, but several disposed around the edge of a 6-inch pot soon make a well-furnished plant. The compost for these and also for established specimens may consist of equal parts of peat fibre and sphagnum moss, but the root being larger and more fleshy than usual in the genus, plenty of large rough lumps of charcoal and crocks or potter's ballast may be mixed with it, and the drainage should come in for special care.

The best time to repot established specimens is soon after the flowers are past, but before the young basal shoots commence to root on their own account. Disturb the roots as little as possible, but take care that nothing in the way of decayed roots or sour potting material is left behind, as this makes the new compost close and heavy at the start, and is bad for the new roots. All such then must be cleared off, and the plants put into clean pots and new sweet material. Then when new roots are produced they push freely into this, and are able to carry plenty of sustenance to the forming bulbs. This is rather an important point in Orchid culture, or, rather, in the culture of this class of Orchid, for if disturbed at the wrong time the pseudo-bulbs are deprived of the nourishment that they require by cutting off the roots that should supply it.

The base of the stems should not be buried, but sit on the top of the compost, this being brought to a convex line from the rim of the pot. All ragged ends of peat and moss ought to be carefully tucked in with a blunt-pointed dibber, as if left hanging loose it is very difficult to say whether or not a plant is dry at the roots. And this, by the way, leads me to say that no Orchid should be repotted, if it can

possibly be avoided, when the pseudo-bulbs are in the least dry or shrivelled, as the further check given by disturbance of the roots is apt to be difficult to get over.

The plants being repotted should be returned at once to the growing quarters, and being a native of Burmah the East Indian house is the proper place for *D. Brymerianum*. Plenty of light must be allowed, and after the young shoots commence rooting on their own account they will bear almost full exposure to the sun. It would not do, of course, to let the sun shine on the plants in a dry house, but the damp atmosphere causes a film of moisture to settle on the glass at closing time, and though the sun may be full upon the plants no harm will be done to them—in fact, it causes just that quick buoyant atmosphere that is the life of all heat-loving Orchids, and *Dendrobiums* in particular.

D. Brymerianum requires a rather long season of growth, and this is often in full swing quite at the end of summer. The advantage, then, of letting the sun get at the forming growths is twofold. It helps them along at a good pace, and hardens them as they are produced, and here the chief difference between this and the deciduous

FIG. 24.—*LÆLIA ANCEPS WADDONENSIS*.

group is shown. The latter may be quickly grown, in most instances, and well ripened by exposure afterwards, but the longer season needed by *D. Brymerianum* renders this impossible, hence the need of ripening the growth as it is made.

The water supply must be free all through the growing season, and until the pseudo-bulbs are fully developed. From this time it may be gradually reduced, until by midwinter little more is needed by this kind than by the *D. Wardianum*, *D. crassinode*, and other divisions of the deciduous set. With regard to the small pieces referred to above, it is not advisable to dry these much during the first season or two, during which time flowers are not usually looked for. The more growth that can be got into these the better, so give them a good long season by starting early, and watering as freely as possible as long as there are any signs of growth.

The old plants will not, of course, be allowed to shrivel, but the less moisture they get, so that this is prevented, the better. Overhead moisture is permissible in the growing season after the new growths lose the characteristic cup shape until they are fully developed, but it is no advantage during dull or wet weather, or at any other period of the plant's growth, than that mentioned. Insects are not usually troublesome, and should they appear are easily kept in check by the usual means. As mentioned above, *D. Brymerianum* is a native of Burmah. It was introduced to this country by Messrs. Hugh Low & Co. in 1874, and was dedicated by Professor Reichenbach to Mr. W. Brymer, of Dorchester, in whose collection it first flowered, soon after its introduction.—H. R. R.

NOTES ON CARROTS.

CARROTS delight in deep, light, rather sandy soil. The ground must be free from anything which will obstruct the descent of roots, such as stones of large size, and clay. It should be free also from manure in the upper layers, but the subsoil may be enriched with some well decayed when breaking it up and finding it poor.

Trenching is the best method of preparing ground, but it is seldom, if ever, advisable to bring up the subsoil and bury the surface, hence some judgment should be used in the method of preparation. Trenching can be done without reversing the spits of soil. Deep cultivation in the way of double digging and trenching is valuable because it increases the depth to which the tap roots can penetrate downwards in a friable medium. When the tap root has a firm exclusive hold there is less probability of ramifications being originated, thus spoiling the form the main root ultimately assumes.

In wet, clayey, or otherwise unsuitable soils, Carrots have little chance of succeeding. In poor, hard soil they are not worth cultivation. On ground enriched and worked shallow, the crop is not a profitable one, though the short varieties may succeed, but even they prefer a deeper medium. The best situation is undoubtedly one which was well cultivated and enriched for a previous crop, such as Celery. Fork and break down the soil well, but keep the manure under. Choose dry and breezy weather for working the soil, and dry, calm weather for sowing. The seed is light, and may easily be blown away.

The earliest crops of Carrots are secured from frames. Early Short Horns are the most suitable. A layer of soil a foot in depth, but light in character and fertile, is placed upon a mild hotbed. The seed is sown in drills, just covering with soil, and protection given to the frames in bad weather. At other times abundance of light with a due supply of air on all favourable occasions must be afforded. Thin the plants to a proper distance. Immediately the roots are a fair size they may be drawn for use.

A sowing of the same or a similar variety may be made in March on a warm, sunny border for forming a succession. It is not necessary to sow the deeper rooting main crop varieties before April, when the ground is dry and becoming warm. The proper distances to form the drills may be 8 to 10 inches, or rather less in frames for the Short Horn variety, a foot for the intermediate forms, and 15 inches for the larger and longer roots. Sowing in drills is undoubtedly the best, because of the expeditious manner in which the processes of thinning the plants and weeding among them can be carried out.

Sow thinly in shallow drills, previously bringing the soil to a fine tilth by the use of the hoe and rake. When the seedlings have attained to a convenient size for handling pull out the most crowded, doing this gradually and at intervals until the plants have been separated to 4 inches apart for the small varieties, and 6 inches for the larger. After the final thinning hoeing between the rows may be frequently practised, not only to prevent the growth of weeds, but to promote rapid development. Only, however, stir the surface when it is dry.

In moist weather a few dustings of soot will be useful, and when hot, dry weather sets in a layer of short grass placed between the rows is beneficial as a mulch and preventive of attack from the Carrot fly.—E. D. S.

DIGGING AND TRENCHING.

I MAY be wrong, I lay no claim to extra acute observation or intuition, but judging from the letters which have appeared in our Journal following the, to my mind, most excellent note on "Winter versus Spring Digging" from the pen of our old friend and long time instructor of gardening in all its phases, Mr. David Thomson, I think—mind, I only think—that each writer has missed the point or crux of the question which our old practitioner brought before your readers on January 20th. To me, with perhaps some of the inner wisdom which comes to men who are getting old and greyheaded, and reading between the lines of his note, it appeared that this life-long, practical teacher, had not in his mind so much the carrying out of the mechanical practical act, as his desire to excite the brain thought which should govern the carrying of it out; that he was thinking more of the head to guide the hands than merely discussing that which the hands should do. He wanted the thought first, the act second; the thinking to be done and on sound lines from the first principles of Nature's laws, and then he knew that each thinker for himself would eventually do what was right, and he gave his practical lesson as to times of digging from his own experience as an illustration as to how he himself had found out the way which proved best for him, and the principles which had guided him to that course of practice. Simply and solely, according to my thinking, he wanted to get every man to THINK, and as an old man, he knew that, unfortunately with many of us, but especially with the younger men, the act is done first and the thinking about it afterwards.

S. R. Crockett, in "The Men of the Moss Hags," puts the

description of this habit very forcibly into the mouth of one of his characters. Jean Gordon, speaking to her relative William Gordon, says, "Ye Gordons are all alike. Ye aye fight and then reason; its first the blow and then the word." This, in substance, is what she says. I have not the book by me to quote verbally; but it struck me at the time of reading that it was too true of more besides the Gordon family, and I think it specially true as to the tone of the criticism on Mr. Thomson's note on digging. If I am wrong I shall be glad to be set right. I do not complain generally of that criticism; far from it. It has been well done from the standpoint of each writer, and not without humour at times, which is always a saving grace.

My contention is, and is only, that the writers missed the point; did not put themselves in the place of the man they criticised, and therefore drew wrong or false conclusions from Mr. Thomson's premisses. We shall all be the better for this friendly excursion into the garden with our spades, and shall profit by the discussion. Each writer is a practical man, knowing, so to say, which end of the spade goes into the ground, and in our future digging we shall think more and more of why we are doing our digging now rather than then—a then rather than now. As this is somewhat of a homily on thinking it may not be amiss to give from an unusual source for a gardening paper an extract from a sermon by the late Cardinal Newman on the growth of the British mind.

The Briton, he says, is in his own way the creature of circumstances; he is bent on action; but as to opinion he takes what comes, only he bargains not to be teased or troubled about it. He gets his opinions anyhow, some from the nursery, some at school, some from the world, and has a zeal for them, because they are his own. Other men, at least, exercise a judgment upon them and prove them by a rule. He does not care to do so, but he takes them as he finds them, whether they fit together or not, and makes light of the incongruity, and thinks it a proof of common sense, good sense, strong shrewd sense, to do so. All he cares for is that he should not be put to rights; of that he is jealous enough. He is satisfied to walk about, dressed just as he is. As opinions come, so they must stay with him, and, as he does not like trouble in his acquisition of them, so he resents criticism in his use.

Does the Cardinal's cap fit any of us? I feel rather like putting it on my own head, even though I am, of course, striving with all my powers to think it does not quite fit me. I am only sure of one thing, and that is, I am anxious to draw attention to the foundation truths in Mr. Thomson's note; those truths are, that, only by understanding the laws of Nature and following them out in our gardening shall we rise to be "workmen that need not be ashamed." "Age should speak, and multitude of years teach wisdom," and that Mr. Thomson is now doing, to our great benefit, for us week by week in the pages of "our Journal." He will have the teacher's reward, a good conscience.—AN OLD PROVINCIAL.

[Does the conscience of this old and able worker and penman disturb him because he has not endeavoured to teach oftener and more?]

ARTIFICIAL MANURE FOR FRUITS.

ALL fruit trees and bushes needing support will be benefited by the application of artificial manures. A healthy and fruitful tree yielding good crops of fruit should receive each season a complete dressing of phosphates, potash, and nitrogen, while one that is inclined to excessive growth and the production of wood rather than fruit should receive phosphates and potash only, the nitrogen being withheld until it is really needed. Raspberries and Black Currants depend on the free production of young growth for fruitfulness, and should receive a manure somewhat rich in nitrogen to promote free growth.

PHOSPHATES.—In stiff soils, peat or rich garden soils, apply in the autumn or early winter 4 ozs. of basic slag per square yard, followed by 2 ozs. of superphosphate in February or March. In light sandy soils substitute a cheap phosphatic guano or steamed bone flour for the basic slag, making the application at any time between November and February. In chalky soils apply 4 ozs. of superphosphate in early spring, and if the tree be cropping freely a second application of 2 ozs. per square yard should be made in June or early July.

POTASH.—In all soils which are not destitute of lime apply kainit 1 oz. per square yard in the autumn. It can often be mixed with basic slag and applied at the same time.

NITROGEN.—Young trees growing in rich soil rarely lack nitrogen, and care must be employed in applying nitrogenous manures lest coarse rank growth result. If the soil be not destitute of lime either nitrate of soda or sulphate of ammonia may be used with the same result. The quantity applied may vary from half to 1 oz. per square yard, according to the requirements of the case. Sulphate of ammonia can be applied in early spring in conjunction with superphosphate, guano, or steamed bone flour. Nitrate is best applied when the blossoms are just expanding, and if the trees are cropping heavily again at midsummer.

APPLICATION.—Do not exceed the quantities specified. Make the applications at the seasons stated, and aim at distributing the manure equally over the entire area of ground occupied by the roots of the trees.

It should be understood that in the case of strong, deep rooting trees which produce correspondingly strong fruitless growth, that no manures whatsoever can impart to them a productive habit. To mitigate the evil of grossness we must literally cut at the root of it.—EXPERIMENTALIST.

WEATHER IN LONDON.—Snow, hail, rain, frost, and sunshine have all visited us in the metropolis since our last issue went to press, and still winter is not yet. Thursday last was a fine day, but Friday, but all the above climatic conditions except frost, which came on Saturday morning. Traces of it were, however, early dispelled by the brilliant sunshine of the early morning and afternoon. The air was again frosty at night, but changed during the early hours of Sunday morning to rain, which was followed by wind, snow, rain, hail, and sunshine. On Monday, though storm was announced in the "dailies," we had calm; on Tuesday it was fine but cold, these conditions prevailing until the time of going to press on Wednesday.

WEATHER IN THE NORTH.—Since the 16th there has been a cessation of the high winds so prevalent, and the weather has been variable, with latterly another snap of winter. Saturday brought drizzly rain in the forenoon, and the evening was dull. On Sunday the ground had a good coating of snow, and 5° of frost were registered. Monday morning showed 8° of frost, which gave way in the afternoon, and 3° were recorded on Tuesday morning, which was bright and clear. A pretty severe snowstorm is reported from the northern counties. As an instance of the forward state of things I may mention that I cut the first Daffodil (*pallidus præcox*) in my garden on the 16th inst. Others are at least a month ahead of the usual stage.—B. D., *S. Perthshire*.

POT ROOT DAHLIAS.—It is not always easy or practicable to obtain Dahlia cuttings just at the right time for propagation, but pot roots may be procured along with the general seed order from most of the leading seedsmen, and these are of a suitable size for starting in small pots in a genial atmosphere between 50° and 60°. They may if necessary be placed in a size larger pot, keeping close to the glass in an airy greenhouse, and later in a frame, preparatory to planting out in late May.—S.

BOURNEMOUTH GARDENERS' IMPROVEMENT ASSOCIATION.—On the 15th inst., before a large attendance of members and friends, Mr. Arthur W. Sutton, F.L.S., delivered his lecture, entitled "Potatoes—Past, Present, and Future." In the absence through illness of the President, Mr. T. J. Hankinson, the chair was taken by Mr. A. Skinner, Highcliffe Castle Gardens, who briefly introduced the lecturer. A large number of limelight illustrations, including various species and varieties of *Solanum*, experiments in grafting and disease prevention carried out at Reading, and examples of some of the highest types of Potatoes in cultivation at the present time, gave additional interest to the lecture. Mr. Sutton was throughout listened to with much attention, and on concluding was, on the motion of Mr. J. Spong, seconded by Mr. J. B. Stevenson, accorded a very hearty vote of thanks. We are glad to observe from the balance-sheet supplied that the Association is in a sound financial state, but sorry to note the Committee's regret that "the meetings are not so well attended as they ought to be."

ROYAL METEOROLOGICAL SOCIETY.—The last monthly meeting of this Society was held on Wednesday evening, the 16th inst., F. Campbell Bayard, President, in the chair. Mr. E. Mawley, F.R.H.S., gave a report on the phenological observations for 1897, from which it appeared that there had been a marked absence of very exceptional weather during the past phenological year, the most noteworthy features affecting vegetation being the persistent rains in March and the three dry periods of May, July, and October. Until about the middle of May wild plants appeared in blossom in advance of their usual time, but throughout the rest of the flowering season they were all somewhat behind their average dates in coming into bloom. The heavy rainfall in the early spring favoured the hay, which proved the only really abundant farm crop of the year, but greatly impeded the sowing of spring corn. The cereals were, however, much benefited later on by the warm, dry, and brilliant weather of the summer. Taking the country as a whole Oats proved a good crop, Barley an average one, while the yield of Wheat was somewhat under average. There were also fair crops of roots and Potatoes. It was owing more to the dry spring and summer and the sunless autumn of the previous year than to the moderate frosts and cold winds of the spring of 1897 that the fruit crop was such a very light one. Apples, Pears, and Plums, and especially the latter, yielded badly, while the small fruits were in most districts only average crops.

UTILISING TREE PRUNINGS.—In removing branches from deciduous trees such as Lime, Sycamore, Oak, Beech and Birch, the most suitable portions may be prepared for Pea and Bean sticks. Shape and point them now while the wood is soft. They will then be ready for use, which will be an advantage at a busy time.—E. D. S.

A RIPE WILD STRAWBERRY.—It may be interesting to your readers to know that on February 14th I picked from the hedge bank a beautiful ripe Strawberry, the fruit well developed, fairly coloured, but lacking in flavour. Is not this evidence of the mild winter we are passing through? May I claim to be the first to have picked a ripe Strawberry in the open air in the year 1898?—S. PAUL, *Castleton, Cardiff*.

NARCISSUS MINIMUS.—The first flower opened here on February 17th, which is twenty-three days later than Mr. Arnott's at Dumfries, N.B. (page 146). Perhaps your correspondent's plants are growing in an exceptionally warm corner, or how are we to account for this great difference? Mine have only the shelter of a wall on the east side 12 feet high, and 10 feet from the plant in question, and they have been established there for several years. I do not find this *Narcissus* flower earlier when lifted and dried off, as your correspondent suggests. Unfortunately I have very few bulbs of it to experiment with, but half a dozen had to be removed last year. They were dried and replanted early; nevertheless they will be eight days later before they open the first flower, although practically side by side with the others.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

THE GREAT PARIS EXHIBITION OF 1900.—The first meeting of the Royal Commission for the Paris Exhibition of 1900 took place on Friday last at Marlborough House, his Royal Highness the Prince of Wales in the chair. In describing the scope and magnitude of the Exhibition, his Royal Highness said provision will be made for the display of every kind of art, industry, and manufacture. The guiding principle is that similar products, from whatever part of the world they may come, shall be shown side by side, and in this respect the Exhibition of 1900 will differ from its predecessors, in which the products of each country have usually been collected together. It was further stated that while a grant for the encouragement of and representation of national industries had been made by Germany of £250,000, and by the small State of Switzerland £66,000, the grant by the Treasury of the United Kingdom is only £75,000, and a considerable increase is hoped for. A number of sectional sub-committees were announced, and under the head of "Agriculture, Food, Horticulture, Forestry, Fisheries, and Wild Crops" we find the members comprise the Earl of Crewe, Duke of Fife, Earl of Dudley, Earl of Jersey, Earl Spencer (Chairman), General Sir Redvers Buller, V.C.; Mr. Horace Plunkett, M.P.; Sir Edward Grey, M.P.; Sir Trevor Lawrence, Sir George Russell, Sir Jacob Wilson, Mr. Thistleton Dyer, Mr. Laurence Grattan, and Mr. Paul J. Madden.

THE SHREWSBURY PRIZE SCHEDULE.—Between the familiar buff covers of the schedule for the present year we find that the sum of £950, apart from medals, is offered for prizes. The great summer show will be held on August 17th and 18th, entries closing on August 10th. The schedule comprises 196 classes, and apparently some 800 prizes. Provision seems to be made for practically everything ornamental and useful that is produced in gardens. Besides allocations of £52 in each of the two large group classes, and £45 in the specimen class (thirty plants), a silver cup, value £25 or cash, is provided for a new class of twenty stove and greenhouse plants, not less than twelve to be in bloom. A change is made in the "floral designs" class, which now reads "six bouquets and six baskets of cut flowers, plants, Ferns, and cut foliage allowed for decoration; space 10 feet by 5 feet. Prizes £15, £12 10s., and £10; a silver cup, given by the President, T. Kynnersley, Esq., with the first prize." Combinations of great beauty may be anticipated. The "decorative dessert table" class, of fruit, plants, and flowers, which was one of the great successes of last year, is to be repeated; and the sum of £45 distributed *pro rata* with the points awarded, as five prizes, the number of points to be placed on the exhibits. On the same principle £25 is offered for distribution in five prizes in the re-introduced "garden produce" class of fruits, plants, vegetables, and flowers (according to the stipulations), arranged in a space of 8 feet x 4 feet by 4 feet 6 inches of tabling. The competitions in this class were too crowded two years ago—not in themselves so much, as in being crushed against each other, which detracted from their individuality. They should, like groups of plants, have clear spaces between them. Valuable prizes are offered by Messrs. Carter, Sutton, Webb, Sydenham, Eckford, and others. The show in its entirety is bound to be of great diversity and magnitude.

— SIR JOSEPH PAXTON.—I should be glad to know of any work giving a biographical sketch of Sir Joseph Paxton.—H. N.

— NITROGEN IN THE SOIL.—The season of the year when the soil contains least nitrogen in a form available for plants is spring. Hence dressings of nitrate of soda applied to Cabbage or Strawberries are more serviceable at that period than later in the year.—E.

— CORRECTING ACIDITY IN GARDEN SOIL.—Lime is very useful to apply to soils that have become somewhat sour and acid owing to the gradual accumulation of humic matter. It combines with the acids in the soil and releases plant food. Basic slag, a by-product in the manufacture of steel, acts similarly on soils containing much humic or organic matter.—S.

— TWO GOOD VARIETIES OF PEAS.—As an early variety of Pea English Wonder is better than American Wonder. Both are wrinkled varieties. The first named grows from 1 foot to 16 inches high, and crops well. As a second early blue Pea, Harrison's Glory is most prolific, grows to the height of 2½ feet, and bears handsome pods. Rich ground and good cultivation is essential.—E. S.

— THE COST OF LONDON PARKS.—Sir John Lubbock has been trying to make a point against the London County Council on the ground of the cost of the parks. There is no more popular branch of the Council's work than its splendid management of the parks and open spaces under its care, and the cost of maintenance, calculated after Sir John Lubbock's manner, by the acre, is wonderfully cheap compared with the cost of some of the royal parks with which the County Council expenditure is compared. For example, if you are going to divide your cost by your acreage, the sum voted in the Estimates for the maintenance of Hyde Park, St. James's Park, and the Green Park is £36,650, for a combined acreage is a little over 500, or between £73 or £74 an acre. The expenditure per acre complained of on the part of the County Council is £28. The absurdity of a calculation by the acre in the case of the parks is shown by the comparison of the cost of the royal parks above mentioned with Richmond Park, which costs the county £2250, but is of so large an acreage that, measured in this way, its cost is a little less than £1 per acre. The County Council's park expenditure includes the wages of constables who patrol the commons and open spaces for the protection of the public and their children, and many other charges which have little to do with acreage.—("Daily News.")

— A VERY MILD WINTER IN IRELAND.—Probably the proverbial oldest inhabitant cannot remember a milder winter than that already passed. Most of us remember very severe weather after mid-February; but in the south of Ireland it is very unusual, and never of long duration. It is providential, so far as the humbler classes are concerned, whose daily dietary the Potato still forms so large a fraction, and which in many districts failed badly. I shall not harrow your readers by a speculation as to what might have been the consequences had the winter—unfortunately, not yet quite over—been unusually severe. Looking through my garden (which is a comparatively small town one), I notice several plants continued to grow and bloom the whole winter through, notably Mignonette, Violas, Pansies, and many Ten-week Stocks; while Gladioli, several bulbous Lilies, Irises, Columbines, and Anemones never ceased growing. Such hardy Tea Roses as Gloire de Dijon, Madame Bernard, and even Devonensis and W. A. Richardson never lost a leaf, and have now flower buds half an inch in diameter. Some of my neighbours, with specially constructed rock gardens and alpine collections, can produce lists of flowers that would be reasonable two months hence. Indoors, the greenhouse and vinery show precocious progress, and indicate an unusually early season. The great look out for the next month or more, however, will be the fruit crop. Some Pears are unusually forward. One expects Jargonelles to be early, but Beurré Superfin and Bergamot are bursting into bloom; and others, like Bon Chrétien and Beurré d'Amanlis, are masses of bloom buds. Some of these were equally so last year; but, alas! a "killing frost" one night "cooked them." I had tried folds of fish netting, but it proved useless as a protection. Except Irish Peach, Apples are still dormant; but Plums are preparing to burst open their fruit buds, especially Victoria, Green Gage, Transparent, Pond's Seedling, and Orleans. I have protected a Nectarine and Apricot that promise well on a south wall. In the farming world, everything speaks of an early spring. Young January lambs are frisking about. The fields are unusually green, the growth of grass having never been checked. Several instances of young thrushes and blackbirds are related; notably thrushes at Ballygowan, co. Down, and blackbirds at Newtownbarry, co. Wexford. The reported presence of the cuckoo is, however, doubted.—W. J. MURPHY, *Clonmel*.

— THE GROWTH OF LAWN GRASS.—It is evident that the mowing machine will soon be required, as the grass is becoming quite thick, long, and luxuriant. March is usually soon enough to commence cutting, but should the present mildness of the weather continue it will be essential to make a start earlier.—E. D. S., *Gravesend*.

— ESSEX MANURING EXPERIMENTS.—In some recent experiments in manuring in Essex the following results were obtained; but they only endorse principles which have previously been determined by some of our leading agricultural chemists, hence they are valuable on that account. (1) Phosphate manures both increase the quantity and improve the quality by increasing the proportion of Clover. (2) Nitrogenous manures increase the quality, but decrease the proportion of Clover. (3) Lime increases the proportion of Clover to a remarkable extent.

— WINTER AT LAST.—It is reported that South Buckinghamshire and Bedfordshire experienced their first real touch of winter on Monday night and early on Tuesday morning, when a succession of blinding snowstorms prevailed. The weather was bitterly cold, and farmers welcomed the change, as the cereal crops were in too forward a state. Heavy falls of snow have been experienced at Bath, Cheshire, Devonshire, Dorset, and Somersetshire. Severe weather is said to have set in in the Fen district; on Tuesday morning 13° of frost were registered, and 18° at Market Harborough.

— HORSFORTH GARDENERS' IMPROVEMENT SOCIETY.—A lecture was given on Monday evening, February 14th, at Horsforth, by Mr. W. A. Clarke of York, who took for his subject "A Ramble Through the Lake District." The lecture was of a very instructive character, all the principal mountains and lakes in Westmoreland and Cumberland being fully illustrated by lantern slides, showing different sections of the mountains inhabited by plants of various kinds. The meeting was well attended by gardeners from different parts of Yorkshire. At the close a vote of thanks was given to the lecturer, which terminated a pleasant evening.—P.

— EARTHQUAKE EFFECTS ON PLANTS.—Mr. W. Helps, writing to the Agri-Horticultural Society of India under date 14th August, states:—"A most remarkable thing has happened to all my Papaya trees since the earthquake. I am sending you some of the fruit to see the condition they are in, and you know what fine ones I had. The fruit I am sending you were the same size as when the earthquake took place on 12th June, so that growth in the fruit has been stopped entirely in some remarkable way since then, but not in the plant, which is still growing and flowering in the usual way. It is not one plant only affected, but every one I have. Can it be the earthquake I wonder, for all plants are very healthy looking? Fruits that have formed outside the influence of the earthquake, a foot or more above where the specimens have been taken from, are growing, and are from three to four times the size of what I send you." The Secretary of the Society writes:—"The specimens received were the size of an ordinary duck's egg. In the Society's gardens it has been noticed that little or no progress has been made in the growth of Papaya fruit since the earthquake." The foregoing is taken from the Society's printed proceedings for July to September, 1897.—("Indian Gardening.")

— NOT THE PLACE FOR GARDENERS.—A recent visitor to the home and farm of Rhodes in Rhodesia has given the following description of it. The farm at Inyanga is about 5000 feet above the level of the sea. Its size is about 3000 acres, and the house stands in the middle of it. It is without fence or hedge of any sort, but is well watered by streams from the mountains, and the soil being particularly rich almost anything could be grown there if it were not for the locusts, which for two-thirds of the year swarm in countless myriads, eating every blade of grass and leaf, in fact everything green on the farm. The kitchen garden being a particularly favourite spot of theirs, it is almost impossible to grow vegetables or to get any fruit. Woe betide the spot which they may select for their night's resting place, for it is brown and dried up next morning as though parched by a long drought. It has truly been said that God's hand rests heavily on this land, for the plagues of all Egypt seem to have settled on Rhodesia, as, in addition to locusts, drought, flies, and fevers, there are rinderpest, scab, tsetse fly, ants, sand storms, whilst the fatal black water fever and painful jigger insect are by no means unknown in the Umtali district, making life in our new territory almost unbearable to Europeans. Little wonder is it then, to find prospectors and miners leaving this part of the world to risk the cold of Klondyke in preference. It could scarcely be anticipated that the name of the home is "Fruitfield."

— **STIMULANT FOR GRASS.**—Kila dust is a manure which acts quickly upon grass, causing a strong and luxuriant growth. It is a nitrogenous and potassic manure, and may be applied at the present time, distributing evenly.—E.

— **BAMBUSA PALMATA.**—Of the dozen or more dwarf, hardy Bamboos, this is probably the handsomest in habit and foliage. When grown in fairly good soil in a position where it is protected from cold winds, it quickly makes a large mass, and forms a pleasing change from the ordinary run of evergreen shrubs. Two large masses are to be seen in the Bamboo garden at Kew. It there grows to a height of about 4 feet, with leaves 1 foot long by $3\frac{1}{4}$ inches wide. It suffers more from cold cutting winds than from frost, the edges of the leaves being turned brown, hence the need of shelter from the north and east. Like other Bamboos it requires plenty of moisture, consequently it should not be put in places where the ground becomes very dry in summer. When fully established a top dressing of decayed leaves and cow manure should be given every spring.—W. D.

— **DO POTATOES NATURALLY DETERIORATE?**—Reading over the latest epistle to your readers from the apostle Mr. Fenn—or shall I now say the patriarch, for he is verging on to eighty years—I was reminded of a fact of which he informed me a few months since, that his crops of his own raised Potatoes were last autumn of the best he had ever lifted. They were indeed as good as Potato crops could be. I have on several occasions seen these said stocks lifted on the same ground on which they have grown for twenty years, and have always found them good, Mr. Fenn varies his crops by planting rows of Potatoes wide apart, and has Cauliflower or some similar crop planted between. Then the following year the Potatoes come where the green plants were. That is not culture according to Cocker, but it is according to Fenn. Now it has often occurred to me that if varieties of Potatoes do deteriorate, as is often said of them, how is it that Mr. Fenn's, some of which have been raised over thirty years, probably thirty-five years, and the stocks of which he has grown himself, either at Woodstock or Sulhampstead, have rather improved in robustness than have lost strength; and if his, why not all others? I do not believe the deterioration theory where culture and storing are good. The Asbleaf Kidney has been with us over sixty years, and it is good as ever. That is doubtless due to thorough maturing, and because liable to sprout early, very careful keeping through the winter. Mr. Fenn has never allowed his seed tubers to be wasted by bad storing. Could our Potato patriarch but live other eighty years, no doubt he would still have as good as ever the fine varieties he raised so long ago. We injure Potato constitutions by our bad practices.—A. D.

— **PROHIBITION OF AMERICAN FRUIT INTO GERMANY.**—Reuter's Agency transmitted from Berlin on the 4th inst. intelligence of a rather serious nature relative to Californian Pears. Here is the message that appeared in the "Daily News." The official "Reichsanzeiger" publishes the following:—"The report published by the American Agricultural Department on the San José shield louse gave rise to an official inquiry here into the circumstances under which fruit is imported from America. On January 29th Professor Frank found on some Pears which were obtained from a consignment of Californian fruit, entered in the Hamburg free port, numerous living shield lice, in a condition to propagate, which the Professor found to be absolutely identical with the true San José shield louse. He consequently expressed the opinion that the home fruit cultivation was exposed to great and imminent danger by the importation of American fruit. A conference of other important specialists and the reports of the Imperial Office of Health confirmed this view in every point, and thus the necessity of prompt measures of protection was fully demonstrated." The "Reichsanzeiger" goes on to describe in connection with the publication of the Washington Agricultural Bureau, the extraordinary perniciousness of the San José shield louse, as well as the measures which various American States, notably Oregon and British Columbia, have taken against it. The official organ then continues:—"It is thus the unavoidable duty of the Government to give efficacious protection to the home fruit industry from the threatening danger of disease. Therefore is the importation of living plants and fresh plant refuse entirely prohibited, subject to the condition that at the port of entry of the said imports investigation of the consignment establishes the presence of the San José shield louse." The "Reichsanzeiger" shows by the example of the phylloxera the danger of not adopting immediate measures of protection, while contrariwise the Colorado beetle was kept out in time. The journal announces the regulations which are to be adopted internally to combat the shield louse, and expresses the hope that the German fruit industry, on which a large community depends for its livelihood, may thus be protected from danger.

— **WOOD ASHES FOR FLOWER GARDENS.**—There is no particular difference between equal weights of ashes from hard or soft wood. The reason for the erroneous common opinion on this point is due to the lightness of soft wood ashes, which makes it necessary to use a very large bulk of them to get the equivalent of a small bulk of hard wood ashes. As to using ashes as a substitute for stable manure where the latter cannot be obtained, it must be said that ashes are only a special fertiliser containing potash and a little phosphoric acid. Stable manure contains these and adds a considerable content of nitrogen, which is usually the greatest need in flower growing. For this reason ashes do not make a good substitute for a stable manure, but in ashes and nitrate of soda the various needs of the plants are ministered to. If leaf mould is to be had, its use in connection with ashes should produce good results.—("American Agriculturist.")

— **THE HESSLE GARDENERS' SOCIETY.**—A meeting of the above Society was held on February 15th, when the popular member, Mr. C. Lawton, gardener to W. H. H. Broadley, Esq., Welton House, Brough, read an interesting and practical paper on "Greenhouse Plants and Their Culture." The essayist commenced by describing the most suitable structure, method of ventilation, and stages, passing on to the general management. In the cultural portion of the essay he confined himself entirely to the hardwooded section, and anyone who has seen the splendid and well cultivated plants belonging to this class at Welton House would not attempt to criticise Mr. Lawton's method of cultivation. There was a very large attendance, and a good discussion followed, the essayist replying to his numerous questions in a masterly manner. Mr. J. Barker showed several pots of Narcissus in variety, and Mr. F. Mason, gardener to Alex. Smith, Esq., Woodleigh, Hessle, showed Cyclamen persicum in twelve varieties. A vote of thanks to the essayist terminated the meeting.—G. W. G.

— **THE MUNICIPAL PARKS OF LONDON.**—Lieutenant-Colonel J. J. Sexby, Chief Officer of the County Council Parks Department, has written a history of the municipal parks, pleasure grounds, and gardens of London, which will be published in May next by Mr. Elliot Stock. The book will contain about 200 illustrations. Colonel Sexby has devoted a great deal of attention to the preparation of this work, in which he will describe not only the leading features of the County Council's parks, but will also recount their history and associations. He has been engaged on this important work for several years, and has collected all local and other information which can possibly be obtained on the subject. No one is better qualified to write a history of London parks, as during the period that Colonel Sexby has been the head of the Parks Department of the County Council the area of the parks has been increased by over 1000 acres, and the special facilities for increasing recreation and public enjoyment introduced, which have made the London parks known throughout the world and the envy of other towns. ("London.")

LEEK CULTURE.

ON reading the excellent and practical article on the culture of Leeks on page 108, I was struck by a sentence from which I and many others will differ. I refer to the following:—"Earthing them is a mistake; nobody ever produced good Leeks in that way." The latter half of this sentence is, I think, too sweeping an assertion to pass uncontradicted, for many of our best growers grow their Leeks in that way.

In a contemporary, "The Garden" (vol. xliii., page 156), the late John Downie gave some interesting particulars regarding the growth of Leeks in Berwickshire as follows, some sixteen or seventeen years ago:—The late Mr. Henry, then gardener at Broomhouse, Berwickshire, was considered the best Leek grower in the country. On the 24th November, 1866, six of Henry's hybrid Leeks were lifted, cleaned, weighed, and measured. The following was the result:—

Leek No. 1,	circumference	12 $\frac{1}{4}$ inches;	weight	5 lbs.
" " 2,	"	11 $\frac{1}{2}$ "	"	4 lbs. 14 ozs.
" " 3,	"	10 $\frac{1}{2}$ "	"	4 lbs. 12 ozs.
" " 4,	"	9 $\frac{1}{2}$ "	"	4 lbs. 10 ozs.
" " 5,	"	8 $\frac{1}{4}$ "	"	4 lbs. 8 $\frac{1}{2}$ ozs.
" " 6,	"	8 "	"	4 lbs. 7 $\frac{1}{2}$ ozs.

Total weight of the six Leeks... .. 28 lbs. 4 ozs.

Two of the leaves when stretched out measured 11 feet in length, and varied in breadth from 8 to 14 inches.

I may add that I knew the late Mr. Henry referred to personally, and have seen his Leeks growing many a time, and for competition purposes he always grew them in trenches like Celery, and earthed them up. Thus we see that good Leeks have been produced in the way in which "Old Grower" said nobody could produce them.—W. H. W.

LAWNS AND ALLIED SUBJECTS.

THIS common, homely subject, lately broached by a brief article in these pages, plays so important a part in all phases of picturesque or ornamental gardening that a fairly comprehensive survey of it may not be inopportune at this particular season; hence it is proposed, in the first instance, to study the ethics of lawn formation from a picturesque point of view—which, happily, are also conducive to good management and keeping—and then to follow up the various details on the lines of sound construction, which are not only capable of making our lawns features of beauty from their creation, but in their permanency. One thing is worthy of consideration at the start—viz., that as we are unable to evade the fact that the labour of keeping our lawns as they should be kept is no despicable figure in the annual bill of a garden's expenses, such should not be left out of our preliminary calculations, and I hope to show that at a minimum expense of labour the maximum of satisfaction is obtained, provided that forethought gives due consideration to these matters.

To view this subject as it should be viewed, or what may be termed the most important parts of it, we must for the nonce glance at it from the windows of what may range from the stately home to the picturesque villa, and in doing so the operations of the indispensable lawn mower can hardly fail to be regarded as a necessary evil. I have, indeed, heard stronger language used which, when toned down, admits of no other interpretation than that of the constant mowing being an intolerable nuisance; for there are places where, from such time the "noiseless" (?) one commences operations with the cuckoo until it ceases with the flitting of the swallows, it is so persistently in evidence that one may readily endorse, if not the remark, the feeling which prompted it. This should not be; no more, in fact, than that in our domestic arrangements the sweeping and garnishing could be tolerated from early morn till dewy eve. I may here digress by remarking that few gardeners, possibly, know better than the writer the difficulties to be met in this respect, to illustrate which I may mention one particular place where the whirring wheels dared not be heard before breakfast time, 9 A.M., or after luncheon at 2 P.M., and after the latter hour all workmen on the Italian garden had to be conspicuous by their absence.

Interdicts similar to the above applying to a large extent of ground are not matters to be lightly regarded where high keeping is a *sine qua non*; but, upon reflection, the principle is right. *Apropos* of this, I occasionally through the summer visit one of our best kept public gardens, and at whatever hour of the day or day of the week such happens, one never is able to view the charming central lawn in all its pristine beauty, for mowing in some shape or form appears to be always in evidence—the season through the operation is never finished. Whether in this case it is unavoidable, I know not; but in private places it, to me at least, seriously detracts from the enjoyment of this grand feature of our gardens. Yet, on the larger scale, where high art in the garden is exemplified in the Italian style, the evil, if evil it be, is probably least in evidence, for we have here a boldness of design which includes open stretches of lawn so disposed as to facilitate the work of mowing which does not always obtain with a totally different arrangement of the grounds.

This brings us to what, I think, is worthy of attention, being, too, of more frequent occurrence, embracing as it does the very large section of what may be termed the picturesque in contradistinction to the purely classic, which admits of few liberties being taken with it. Needless to say, no hard-and-fast lines can be laid down, for there is not, I suppose, a single instance where local circumstances do not sufficiently assert their individuality to warrant the assumption that a special study of character is alone able to give the best results. I cannot but regard our subject as one inseparably bound up with landscape gardening. Is it not, indeed, the very folio upon which its best characters are traced? Hence, perhaps, no apology is needed for enlarging so much upon the text.

In the picturesque treatment (not classic) of grounds in contiguity to the residence so many temptations occur for breaking up the more important portions of the greensward by various phases of planting as well as by a redundancy of walks, that, although not always courting condemnation from a picturesque point of view, it militates more or less seriously against good management of the greensward, including the quick and effective performance of periodic mowing, consequently the scenic effect is correspondingly stultified. This, of course, chiefly from the labour side of the question; but there is a broader and, I think, higher view that insists itself upon our notice in spite of that variety which may, or may not, be charming, for the taste is questionable which prompts the planter to bring as many beds as he can carve out, or as many trees as he can conveniently dot down within sight of the windows. Much quiet beauty is thus sacrificed. I have heard it

remarked that the flower beds do so much for the lawn; to me, at least, it appears to be *vice versa*—that the lawn is able to do so much complementary work that too much, far too much, is literally put upon it.

To trace effect to cause in so far as relates to the breaking up by planting or other means of many a charming lawn-frontage to a picturesque residence, the term may be admitted in contradistinction to classical outlines which need no longer detain. We may go back to the earlier days of the bedding craze, and also include the introduction of various Coniferae which claimed a great share of attention; so much so, in fact, that whilst the former inculeated much carving out and cutting up of the lawn, there seemed an inordinate desire to dot *hic et ubique* a Wellingtonia, a Picea, a Pinus, or what not, and to bring particular specimens into prominence by placing them in the immediate foreground—in view of the windows. Having a vivid recollection of how to spoil a lawn, it may, although roughly sketched from memory (fig. 25), serve to illustrate this. It is representative of the south front of an old Tudor residence bounded on the north by a public road. It delineates what is still frequently to be seen. A replica of the outline is also given (fig. 26), which cleared consistently, not ruthlessly, gives a bold sweep satisfying to see, easy to keep, and lending a dignity to the building which with the dot and carving system can never obtain. It must be mentioned that fully two-thirds of the beds have recently been turfed over to the general benefit of all concerned but the trees, which have grown apace; the liberty of sacrificing them has only yet been done on paper, as shown, but sooner or later the great mistake will have to be rectified, and it has long been under consideration.

In relation to keeping alone, it is obvious how much unsatisfactory labour is entailed, and although I have often watched the agility displayed both by the man who controls the machine and the boy who controls the pony, together with the marvellous manner in which they conjointly manœuvre in and out and round about to snip off a bit here and a corner there in their anxiety to save the scythe, not to speak of wet weather, when a dozen repeated turns at particular corners leave greasy patches, one cannot regard such work as a labour of love.—SYLVA.

(To be continued.)

THE FLORISTS' PHLOX.

GRACEFUL and effective as are the original plants from which our Phloxes of the present day have been raised, they are defective when compared with their descendants. The florist, with his trained and skilled eye and expert hand, has seized upon their points of beauty, and developed them almost beyond his utmost hopes. Not often do we see the old tall Phloxes, once the delight of their growers, and favourites with artists in flowers; but when we do meet with them, we are compelled to admit their inferiority as compared with those of more recent origin.

In purity, brightness, or depth of colour; in size, form, and texture of flowers; and in massiveness of spike, the modern florists' varieties rank far above the older sorts or those from Nature's garden, where the law of the survival of the fittest discourages flowers less well adapted to the rough conditions under which they grow. In our gardens, however, where shelter is found, together with suitable soil, and a sufficient but not superfluous supply of moisture, the flowers of the most advanced types not only grow, but afford the means for still further improving the race.

For the original parents of our modern Phloxes we are indebted to North America, a part of the globe which has given us many of our most admired garden flowers. For the florists' Phlox itself we owe gratitude to raisers of various countries, as English, Scottish, and Continental growers have all contributed their share of the work. In the early days of its improvement, English growers took a leading part, followed hard by Continental raisers, and then by Scotsmen, who gave us many good varieties. More recently the Phloxes which have met with the favour of the Floral Committee of the Royal Horticultural Society have principally been of French origin.

Several of these varieties have, in the eye of the writer, the defect of too flat a spike. Their great merits are the size of the individual pips, their texture, and their intense colouring. Some of the scarlets are of the most vivid colouring, and were these merits combined with the symmetrical spikes of some of the older ones, there would be nothing lacking. A marked tendency on the part of raisers of late has been to reduce the height of the plants, and in some flowers this has been effected without the loss of other points. The judging code of the R.H.S. gives these, and they may be thus summarised:—Stem stout, strong and erect; spikes full of bloom, dense, and of symmetrical shape; the blooms stout in texture, flat, and quite circular in form, with clear, decided colours.

The colours of the Phlox are most varied. There are whites of

various degrees of purity; some are without a tinge, others are almost cream-coloured, and others, again, have just a sufficient tinge of blush to give them warmth. There are pinks, roses, scarlets, vermilions, pale purple, deep purple, slaty blue, and the blue-purple of one named Iris is the nearest approach to blue in the florists' Phloxes. These shades of purple and blue are not much admired, however, and do not gain in favour, although at times useful on the exhibition stand. There are also striped and "eyed" blooms. The latter are more appreciated than the striped varieties, and many are very attractive, if a little formal. In some the eyes are white or light coloured with a dark margin, and in others this is reversed, the eye being darker than the body of the flower.

There are two races of the summer and autumn flowering Phloxes. These are divided into early and late flowering varieties. The former are said to have originated from *P. glaberrima* (*P. g. suffruticosa* of some), and the latter from *P. paniculata* and *P. maculata*. The early flowering section are as a rule dwarfer, and have not reached so advanced a stage of beauty as the others, but are nevertheless of great merit.

The florists' Phlox is of much value in the garden. Massed in beds or borders it is very effective, and planted in the mixed border it gives much beauty, although among other flowers its special wants cannot be so well supplied, and its distinctive charms are displayed to

exhibition must not be cut much before going into the stands, but if this cannot be avoided the stems should be deeply immersed in water for some time.

The Phlox is propagated by division of the roots either in spring or autumn, and by cuttings taken off in spring or summer. Plants raised from cuttings are preferred by exhibitors and those desiring more vigorous growth. The cuttings may be inserted in frames or pots, and will root more rapidly if a little bottom heat is at command. Short lengths of root placed in pots of light soil in winter will also grow, and in the case of scarce varieties leaves with a bud in the axil of the stem are sometimes used as a means of propagation. Young plants of small size ought to be kept in a frame during winter. New varieties are obtained from seeds sown as soon as ripe, or in spring. These should not be sown in heat, but in the open ground or a cold frame. The seedlings appear very irregularly, and some only after a considerable time.

The question of the retention of old plants is one which has been much debated. A plant which is in good soil and receives regular attention in the way of mulching, surface dressing and watering in summer, will last in good condition for several years if the stems are thinned out. Many, however, prefer to raise young plants every two or three years, and there is little doubt that this method gives very satisfactory results.

FIG. 25.—THE DOT AND CARVING SYSTEM.

FIG. 26.—THE LAWN IN ITS BEAUTY.

an inferior degree. It requires rich feeding and some attention to enable it to develop its beauty to the fullest extent. Beds on the grass or in front of shrubberies are pleasing features of many gardens.

To do it justice the Phlox must be well grown. There is little hope of full success with it or other florists' flowers unless its requirements are carefully attended to. This is due to no want of hardiness, but is simply because the points we have developed require good treatment to bring them to their highest stage of beauty. The first essential is a good and rather heavy soil. It will grow in poorer soil, but something more than mere existence is needed if we wish to have this fine flower in perfection. The good soil at command, it must be properly prepared by bastard trenching, and the incorporation of an ample quantity of animal manure. Nothing equals horse or cow dung, which to use depending upon the soil, light soil requiring the latter. It ought, as a matter of course, to be well decayed. In the beds thus prepared the plants may be planted in March or April, the surface being afterwards mulched with similar manure. They should never be allowed to suffer by want of water, and in order to give greater vigour a little of some of the standard artificial manures may also be applied with the water, only the quantity recommended on the package being used.

If grown for exhibition purposes, Phloxes should only be allowed to make two or three stems, the others being thinned out. This will be found to give larger spikes and finer flowers, besides giving the former more room to develop. To prevent injury to the spikes each stem ought to be firmly tied to a light stake. In wet and stormy weather protection should be afforded to the flowers. The best method is by means of three stakes or stout wires fixed in the form of a tripod. A frame of wirework covered with canvas is placed over the top of this at night, or when protection is required. Phloxes for

The selection of a list of the best Phloxes is a task of great difficulty, and that now submitted makes no pretensions to including all the best. It is merely a selection of varieties of high merit which will give satisfaction if properly cultivated.

It is to be hoped that our British seedling raisers will again take up in earnest the improvement of the Phlox. It is not yet perfect, and the writer has within the last year or two seen some seedlings of great beauty raised in a private garden from flowers of the highest quality. Some of these will probably find their way into the hands of the trade, and one named "John Maxwell," in honour of a worthy friend of the writer's and a true florist, will compare favourably with any as yet before the public. In the following selection an old Phlox (*Coccinea*) is included. For bedding it is difficult to surpass, although inferior in size of pip to the newer varieties.

SELECTION OF PHLOXES.

Early Flowering Varieties.—Charles Downie, rose, crimson eye; James Thompson, deep rose; King of Purples, purple; Lady Halliburton, white; Lady Napier, white; Marquis, rose, crimson eye; Mrs. J. Hope, white, crimson eye; Purple Emperor, light purple; the Marquis of Huntley, veined rose; and White Swan, white.

Late Flowering Varieties.—Amazon, pure white; Aurore, orange scarlet; Bayadère, pure white; Coccinea, crimson; Cœur de Lyon, lilac; Corneville, dark wine colour; Diadem, white; Eclatant, rose, crimson eye; Eugène Danzanvilliers, lilac, white eye; Eugène Scholt, rose, white eye; Henri Mürger, white, rose centre; John Forbes, pink, crimson eye; Madame Antoine Denis, blush, crimson eye; Mrs. Kinghorn, salmon rose; Pantheon, salmon, white eye; Regulus, rose-salmon, white eye; Roxelane, deep carmine; Sheriff Ivory, salmon; Sylphide, white; and Tourbillon, crimson, white eye.—S. ARNOTT.

THE NATIONAL CHRYSANTHEMUM SOCIETY AND THE ROYAL AQUARIUM.

"My determination's great this enterprise to further."

THUS the opening of the "Drama," on page 150 last week. The utterance has proved true in a manner that the dramatist could not have imagined, or certainly he could not have known of the intention of his first character in the piece.

Mr. J. W. Moorman has issued an eight-page pamphlet, entitled "The National Chrysanthemum Society and the Royal Aquarium. The Society's Shows and Management, with Suggestions for Consideration." After a review of the whole question the author and compiler gives condensed citations from the correspondence which has appeared in the *Journal of Horticulture*, also extracts from other journals, which are in accord with his views. He admits that the "masterly review by 'Spectator'" is beyond his power of abridgement, and therefore publishes it *in extenso*, and concludes as follows:—

WHAT IS TO BE DONE?

"I am sanguine that this controversy must eventually result in the true and lasting interests of the National Chrysanthemum Society, and to that end the following points, in addition to those previously mentioned on page 4, appear to require ventilating at the annual meeting:—

FIRST.—Whether the time has not arrived for the Society to have a paid Secretary and no vote?

SECONDLY.—That it be an instruction to the Committee to inquire and report on what other places (if any) can be obtained for our exhibitions, either by a subsidy, as now, or otherwise?

THIRDLY.—To consider if the time has not arrived when in reliance on our own resources we can proceed on independent lines like most provincial societies, which are in a sound financial condition?

FOURTHLY.—As there appears to be much disquietude arising from the fact that the Secretary is the delegated referee at all our exhibitions, whether the advisability of a change should not be considered in the form of a small Reference Committee or otherwise?

FIFTHLY.—That as the custom of selling the floor space of the Aquarium to trade exhibitors (some of whom are not *bona-fide* growers of Chrysanthemums), and that inasmuch as such sales have driven competitive exhibits of Chrysanthemums into semi-dark galleries upstairs, whether such custom of selling space for a different purpose than that for which the National Chrysanthemum Society was established shall be seriously considered with a view to its discontinuance.

SIXTHLY.—That an Exhibition Committee be appointed to closely examine the question of minor shows with the object of ascertaining their advantages or otherwise, to the Society, and report the results of their investigations to the General Committee.

"Having done what I conscientiously felt it to be my duty in seeking to extricate the National Chrysanthemum Society from an incongruous position, which alienates an important and wealthy section of the community—a section which would otherwise join in placing the Society in the commanding position it ought to enjoy—I now earnestly request the hearty co-operation of all who desire its freedom, independence, and prosperity.—J. W. MOORMAN."

"What is to be done" only time can tell. We have received many letters expressing appreciation of the "Drama," but are bound to say that the great majority of the writers concur with the author's prophetic utterance—"The big braves hang back, I win." One correspondent goes so far as to say that he will be "much surprised if Mr. Moorman has one supporter at the annual meeting." Another writes in a valedictory way as follows:—"Now ye masked mummers, assemble in your thousands in the big 'smoking concert' room of the Handy-Andy Hotel on Monday night next, and when the combat is over shed a tear for the man who is no more."

Let the issue be what it may, we have to congratulate all our correspondents who took part in the memorable discussion on the excellent tone and spirit manifested throughout. Mr. Moorman's epitome is a fair reflex of it, which many persons interested in Chrysanthemum lore will be glad to possess. The pamphlet can be obtained in return for 1½d. in stamps, sent to his address—The Lodge, Victoria Park, London, E.

MR. MOORMAN has kindly sent me a copy of his pamphlet, *re* the recent discussion in your columns, and elsewhere, respecting the connection between this Society and the Royal Aquarium. I am obliged to him for it, and do not in the least complain that he gives my initials prominence in it. Seeing that Mr. Moorman gives me the credit of setting the ball rolling, I can but be reminded of an old saying, "Behold how great a matter a little fire kindleth." What the effect may be on the Chrysanthemum community at large I do not know. Possibly very little. If there were one tithe the desire manifested in relation to the queen of autumn flowers to worship her only for love, no doubt a great change might eventuate, but my interest in the Society has become a thing of the past. I am no longer a member, and its affairs are to me a matter of absolute indifference.—A. D.

NATIONAL CHRYSANTHEMUM SOCIETY—GENERAL COMMITTEE.

THE General Committee of this Society held a meeting on Monday last at Anderton's Hotel, Fleet Street, when Mr. T. W. Sanders presided. There was a good deal of business to be done, and much discussion on matters arising out of the minutes and correspondence, but chiefly of a formal nature. The Foreign Secretary reported on several matters of interest, showing that the work of the Society was becoming more widely appreciated abroad, but particularly in Germany, where Chrysanthemum culture is arousing the attention of growers.

The report of the Classification Committee was then presented, by which it seems that different varieties are sometimes shown so closely resembling one another that it is desirable to lessen the risk of duplicates being shown. Instances were cited of Mrs. Heale and Princess of Wales, Charles Curtis and Major Bonnaffon having been staged in a condition that rendered them almost identical. A good deal of time was spent in reviewing this report, and finally, on the motion of Mr. Crane, it was resolved that the report be referred back to the Committee for them to prepare a list of too much alike varieties. The undermentioned varieties are now classed by the Committee as incurved:—Austin Cannell, Ernest Cannell, General Mauric, Lady Isabel, Lyne, jun., Mdle. Lucie Faure, Madame Ferlat, M. Desblanc, Owen's Crimson, W. Carpenter, Yvonne Desblanc, Mrs. N. Molynoux, Harold Wells, and Sir Trevor Lawrence.

Next followed the draft report, in which the progress of the past year was set forth. Numerically the Society has improved, there having been elected thirteen Fellows and 114 ordinary members, and affiliated societies increased by eleven. The draft financial statement was also considered, and shows the income for the past year to be upwards of £1100. Both of these documents will be laid before the annual general meeting on Monday next in their entirety. The Secretary drew attention to the increasing amount of prize money offered year by year, and pointed out that prizes of the value of over £500 were provided for in the new schedule for 1898.

A communication from the Treasurer, Mr. J. R. Starling, was announced, resigning his office on account of ill-health. A vote recording the thanks of the Society for his long service was passed. The annual meeting of the members of the Society will be held on Monday next, at seven o'clock, when Mr. Sanders, the Chairman of the General Committee, has been requested to preside. Owing to the lengthy agenda the meeting was not over until unusually late.

THE BELFAST SHOW.

I OBSERVE from a communication on page 152 of your last issue, that Mr. Beckett asks me to deal with a complaint made by Mr. Peter Brock, on page 122 of the previous week. I had, of course, already seen Mr. Brock's letter, but considered that, as he was clearly complaining of the judging, if any answer to it were necessary, it would be from Mr. Beckett it should come, and I had not, therefore, proposed to intrude upon your valuable space. As, however, Mr. Beckett appeals to me on the matter, I venture to ask you to insert this letter.

As regards the circumstances under which the bloom was named, I can only say that it was precisely as Mr. Beckett has stated. My instructions to my assistant attending the show were that the bloom was to be labelled, "Yellow Madame Carnot," and the first intimation I had of the affixing of a different description was the evening after the Belfast Show, when I heard of it at Edinburgh, where I had gone for the purpose of the show there, and I was very much surprised that any question had arisen on the matter. As to the description of the bloom as a "Yellow Madame Carnot," I can only say, what is in fact common knowledge to all Chrysanthemum growers, that there was then no standard by which the exact shade of yellow of that variety could be fixed; and knowing that my blooms were from very early buds, I naturally thought that later blooms would come a deeper yellow, and that therefore there could be no possible doubt that it was the "Yellow Madame Carnot," and I named it accordingly.

Having regard to this, and to what Mr. Beckett has already stated, I think all fair-minded men will agree that there is no necessity for me to deal further with Mr. Brock's communication, except to add that it is impossible for him more than myself to say what any other judges would have done if they had been in Mr. Beckett's place; and that I am sure if Mr. Brock had known Mr. Beckett as well as he is known to the generality of growers, including myself, he would not have made such a remark.—W. MEASE, *The Gardens, Downside, Leatherhead*.

COLLARETS FOR CHRYSANTHEMUMS.

WHILE not encouraging the use of collarets as an aid to displaying Chrysanthemum blooms, I should not take upon myself the liberty of disqualifying an exhibitor who made use of them if no mention of them were made in the schedule. I should, however, take care that such an addition did not assist the exhibitor in securing a prize. It is quite easy for a man of experience like Mr. Beckett to tell if blooms are artificially set up by the aid of collarets. The natural "build" of the blooms would point this out. Although not seeing the Belfast Show, I am quite sure the third prize blooms were sufficiently good of themselves to secure their position in the competition, even if there had not been a collar at all employed. How can a judge disqualify a stand of blooms purely because they receive a supposed aid from collars when no mention is made in the schedule? Committees, not judges, are responsible for any shortcomings of the rules or regulations.—SADOC.

NEW FRENCH CHRYSANTHEMUMS.

HAS not Mr. C. Harman Payne (page 153), made a mistake in classifying several of the varieties there named? For instance, -he

describes *Mdlle. Lucie Faure* as a Japanese incurved. He gives it as his opinion that this will probably rank as one of Calvat's best. Surely Mr. Payne is aware this variety has been certificated as an incurved by the N.C.S. Has he copied the descriptions from Calvat's catalogue, forgetting what his own knowledge should have taught him? From so high an authority as Mr. Payne such information is somewhat misleading to those who depend upon public writings for classification of foreign Chrysanthemums. Madame Ferlat is another instance of misrepresentation. It has been many-times staged in England and passed as a true incurved variety. Here it is described as "a grand massive Japanese incurved of great size and substance." This statement is hardly correct; as an incurved Chrysanthemum it is not massive, neither is it grand as I interpret the word. How, then, can the remark be applied to it as a Japanese incurved? *Topaze Orientale* is claimed by many to be a very good form of Chinese incurved. Exception might easily be taken to the description given of Madame Ed. Roger if judged from an English point of view. "This is a most distinct novelty, being of a pale but decided sea green colour." This is the description given of it. One naturally asks how it is a "distinct novelty." Is it the colour that makes it so, or is it the misshapen blooms so often seen on the narrow pointed florets which characterise the variety?—OBSERVER.

EQUAL PRIZES.

I HAVE read carefully the correspondence which my note has brought forth. I must confess that I see no reason to alter my views from the weight of arguments adduced by the various writers. The parallel drawn by Mr. Beckett as to decisions given by judges in racing is not a happy one. In this case it is purely a physical action on the spur of the moment. Not so with flowers, or any other horticultural produce, where so many points of detail have to be taken into account. I, too, saw the disputed groups at the York Show, and heard many comments passed upon them, and I admit these two exhibits required much consideration on the part of the Judges. I was not alone in my opinion (not expressed) that it was possible to find a first prize where so many details admit of comparison, and especially when one of the exhibits contained a host of small blooms closely packed together. On the other hand, it was not difficult to see the other exhibitor might have made more of his Chrysanthemum blooms if he had made them less. This may seem somewhat of an enigma!

I am afraid the instance cited by "W. S." of the action of certain judges at a West of England show does not assist the solution of what is to some an insurmountable difficulty. In the case in point the fault was distinctly that of inability, as the result proved. The *Dahlia* case, quoted, too, by "W. S.," affords another instance of dissatisfaction; it is plain that the cultivators knew where the difference lay in some of the blooms referred to. "W. S." says that the blooms "taken individually were a perfect counterpart of each other that it was impossible to find a determining point." This is surely a case of pitting the knowledge of the exhibitors against that of the judges. Perhaps these were such as "W. S." alludes to in the preceding paragraph? I would ask "W. S.," Could he go into the largest *Dahlia* nursery in the country, cut and stage two stands of twelve *Dahlia* blooms, distinct, that were really equal in point of merit of bloom, staging, and arrangement of colours? He may say yes, because he would, if possible, choose duplicate blooms. I do not think an instance can be cited where two exhibitors of flowers of any kind coming from separate gardens have staged identical varieties. I fancy "W. S." would find the task suggested a difficult one.

I have had a somewhat lengthy experience in judging Chrysanthemums in many parts of the country, and at all the leading shows in times gone by, but I never came across a similar instance to that named by "W. S.," where a cash prize and certificate could not be awarded together as in the instance named. I do not see any difficulty in distinguishing superior blooms in both sections when in opposition. Neither should any judge, if he has experience to aid him, in arriving at a solution of the difficulty. I have many times found a difficulty in selecting the premier bloom in the incurved section, but simply because the difficulty laid in finding a bloom that possessed sufficient points of approach to an ideal specimen. Generally prizes are awarded for the premier bloom in each section; when this is so, the difficulties of judges are lessened. Some adjudicators are so sectional, that they cannot see merit in a bloom if it does not belong to their pet division. Equal prizes are too often awarded under such circumstances. "Forlorn" (p. 108), cites an instance of how a cash prize and a certificate were divided. If "Forlorn" had given particulars of the blooms selected, a better opinion could have been given upon the wisdom or otherwise of the judges. The mere quoting of cases without facts does not advance the argument in favour of the awarding of equal prizes.—NOT A SOLOMON.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE annual dinner was held on Wednesday evening, the 16th inst., when over ninety members and patrons attended. Mr. C. E. Jeffcock, the President of the Society, occupied the chair. Delegates attended from the Walkley Amateur Floral Society, the Sheffield Floral and Horticultural Society, the Rotherham Chrysanthemum Society, the Rotherham Floral and Horticultural Society, the Chesterfield Chrysanthemum Society, and Wakefield Paxton Society. The Leeds and Barnsley Societies were each invited, but no delegates attended. The dinner was held in the large room of the Masonic Hall.

After the loyal toasts, Mr. F. W. Littlewood submitted "The Lord Mayor and Corporation," which was honoured with great heartiness. Dr. Banham next proposed "The Visitors and Kindred Societies," to which several of the delegates replied. Mr. J. G. Newsham, in giving

the toast of "The President, Vice-Presidents, and Patrons," referred to the help given to the Society by those gentlemen, and especially by the President, who was always ready and anxious to do all he could to advance the interests of the growers of Chrysanthemums and of this Society in particular.

The President said the Vice-Presidents, the patrons, and himself appreciated fully the work done by the members, and especially the Committee and the working officials of the Society. They could not help being pleased with the improvement seen year by year, and the trouble taken by growers of Chrysanthemums to introduce novelties season after season. The success of the Society was due very largely to excellent management, and also to the desire on the part of the members of the Society to always be introducing something new.

Mr. A. S. Jarvis, in proposing "The Sheffield Chrysanthemum Society," referred to the fact the institution was sixteen years old. It was not a great age, but they had made great strides, and their Society would compare well with similar societies in any part of the kingdom. Sheffield stood well to the fore in the matter of its Chrysanthemum show, and the greatest credit was due, not only to the officials who worked so hard, but also to the exhibitors who year after year showed such excellent blooms. Mr. Houseley, the Secretary, in acknowledging the toast, referred to the excellent work done by the Committee. To them the success of the Society's work was largely due. He had it on the authority of one of the leading horticultural journals that the Sheffield Chrysanthemum Show held a position which was only third in the whole kingdom. Referring to the progress of the Society, the Secretary said that four years ago they had in hand the magnificent sum of 9s. 6d.; they were now worth over £100. Mr. J. Haigh gave "The Nurserymen and Non-competing Exhibitors," which was replied to by Mr. Artindale.

THE GARDENERS' ROYAL BENEVOLENT BALLOT.

THE remarks of Mr. J. Ollerhead (page 132), of this institution, should not go unchallenged. What are the facts in which he considers he has cause of complaint in his employer's behalf? A man who, I do not doubt, is a deserving candidate, is anxious to be placed on the list of pensioners, but who has never subscribed a penny towards the funds of this admirable institution. Consequently he has to take his chance of being placed on the list with others, some of whom have subscribed for several years. Others, again, are like himself, who in their years of prosperity failed to subscribe to the funds, and now, when the day of adversity has come, they appeal to the subscribers for their votes and interest in their behalf.

I fail to see where the hardship comes in. My sympathy is with those who have subscribed (or widows of such), and who have to stand their chance of election with the above. Mr. Ollerhead says, "My employer and family have subscribed a total of £168," and considers he has been badly treated because his nominee has not been placed on the list of pensioners. I hope the day is far distant before anything so high handed as he hints at may be allowed to have influence with our public institutions.

If all those kind and benevolent people who have so liberally subscribed large sums of money (all honour to them for doing so) to this grand institution were similarly minded as Mr. Ollerhead, and each selected a candidate at every election, on the same lines, he would find the subscribing gardeners throughout the country would make their presence known. Their subscription of a guinea a year, or ten guineas, of hard earned money to constitute a life membership, means really more to them than the £168 subscribed by the family of a gentleman of wealth. Are we to be ignored because fortune has not smiled upon us to the extent of the above mentioned figures?

Provincial gardeners are not able to attend the annual festival, but through the gardening press, and from the annual report issued to all subscribers, we are well informed of what is being done, and have every confidence in those who hold the reins of management. Although the majority of them are personally unknown to me, I believe they have the interest of gardeners at heart, and one has only to read some of the speeches delivered at the annual dinner to know of the many cases of real distress among gardeners, and how they have appreciated the assistance they have received from this noble institution.

I would here appeal to all gardeners, whether young or old, to try and afford a guinea a year to its funds; then, should adversity overtake them in their old age, they may have £20 a year for life simply for the asking, and without the expense of a poll, and also without the risk of offending, or the society of losing a rich subscriber in consequence.—S., *Yorks.*

RHODODENDRON PRÆCOX.—In various parts of the gardens at Kew this plant is now making a fine show. The great objection to its extended cultivation is that the flowers are often damaged by frost before they are over. This calamity has been partially averted at Kew by growing some of the plants in positions where they are sheltered from cold winds, and where the sun does not shine directly on them until midday, the flowers thus thawing gradually. Anyone who has been unsuccessful with this plant, and has similar situations at command, would do well to try the plan. For greenhouse work, either forced for Christmas or allowed to come on naturally for flowering during February, it is among the best of the genus, and is well worth a place in any establishment.—K.

ROYAL GARDENERS' ORPHAN FUND.

ANNUAL GENERAL MEETING.

UNDER the presidency of W. Marshall, Esq., the annual general meeting of this admirable charity was held at Anderton's on Thursday last, the number present being about two dozen. Amongst others noted were Dr. Maxwell, T. Masters, and Messrs. Harry J. Veitch, A. Outram, G. Gordon, J. Fraser (Kew), G. W. Cummins, J. Walker, R. Dean, H. J. Jones, J. Lyne, B. Wynne, H. B. May, W. Bates, J. McLeod, and A. F. Barron, Secretary. The majority of those present were members of the Committee, and it speaks well for the management that the subscribers are content to leave the affairs of the Fund in the present able hands, and do not feel constrained to attend the general meeting to set matters straight.

The adoption of the report was moved by Mr. W. Marshall in brief terms, which added nothing to the statements given above. Mr. W. Bates seconded the motion, which was carried unanimously. The Treasurer, Auditors, and Secretary were re-elected without a dissentient voice, as were those retiring members of the Committee who were standing again. Messrs. A. Outram and G. H. Richards were elected in place of Messrs. H. Ballantine and H. Cannell.

Messrs. R. Dean, H. B. May, J. Walker, and J. F. McLeod were appointed scrutineers of the ballot for the election of children to the benefits of the fund. Eighteen candidates were presented, and the following were elected. Agnes Macintosh, 349; Robert John Smith, 332; Jamesina Baird, 278; Lydia Annie Milne, 275; Hermine Kosbab, 272; William Ewart Holmes, 269; Ruth Amy Worth, 241; Margaret Annie Richardson, 232; and Constance Mary James, 209. Annie Kathleen French, with 166 votes, was elected to the benefits derived from the J. W. Thomson legacy.

THE REPORT.

The Executive Committee, at the close of the tenth year of the existence of the fund—it having been established in 1887—can look back with pride and satisfaction upon the substantial progress made during that decade. The Royal Gardeners' Orphan Fund is now firmly established among gardening institutions, and during the period of its operations, while it has succoured a large number of orphan children, all of them in necessitous circumstances, it has also been able to invest a small reserve fund. Your Committee feel they can heartily congratulate all those constant and earnest supporters of the fund, who, since 1887, have rendered such valuable and acceptable aid.

In submitting their annual report and financial statement, your Committee have to record with some feelings of regret, that the receipts of the past year have not been so satisfactory as could be desired, and would, therefore, urge upon the friends of the charity the necessity of increased efforts during the ensuing year.

One very gratifying feature has to be recorded: the receipt of letters of deep thankfulness from the mothers and guardians of children who have ceased to be chargeable to the fund, owing to the operation of the age limit. One mother, after expressing her sense of most timely help, observes:—"I sincerely hope that my children may help the fund as they have been helped by it."

Besides the ordinary payments of the sum of five shillings per week to orphan children, your Committee have made special grants in necessitous cases to children on leaving school, or being apprenticed to some trade, thus giving them a start in life. The sum of £22 10s. has been expended in this helpful way during the year.

During the past ten years ninety-eight children have derived benefit from the fund; of this number, sixty-two are now receiving a weekly allowance. This number will be increased by those fortunate enough to

secure election to-day. The total amount paid to children since the fund was instituted is £5807 5s.

Another most gratifying circumstance is the amounts received from collecting boxes, the proceeds of concerts, sales of flowers, &c., at provincial flower shows. Among the most important donations are those of £50 from the Scottish Horticultural Association, part of the proceeds of the magnificent exhibition of Chrysanthemums held in Edinburgh in November last, and £26 5s. from the Royal Caledonian Horticultural Society. The Chislehurst Gardeners' Society have contributed £23 12s. 6d., and the Altrincham Gardeners' Society £18 8s., proceeds of concerts. Smaller sums from other societies have been received and proved equally acceptable; such receipts have now become an important source of income, and your Committee tender their most grateful thanks to all who have so materially helped to swell the resources of the fund. The sum of £457 5s. 11d. has been received as a bequest made by the late Mr. J. W. Thomson, of Hayward's Heath, formerly a well-known nurseryman, and invested in accordance with the terms of the will. This legacy will henceforth be known as the "J. W. Thomson Trust."

The annual dinner, held at the Hotel Cecil in April last, was presided over by Sir J. Whittaker Ellis, Bart., and resulted in a handsome subscription list of £635. Your Committee owe a great debt of gratitude to Sir J. W. Ellis for his very able advocacy of the objects of the fund, and tender him their most hearty thanks.

The best thanks of the Committee are also due to the Treasurer, N. Sherwood, Esq., for the warm interest he takes in the fund, and his faithful discharge of the duties of the office he holds; also to their Auditors, Mr. M. Rowan and Mr. P. R. Barr, for their labours in auditing the accounts. The retiring Auditor is Mr. M. Rowan, who is nominated for re-election.

The Committee have to deplore the loss by death of Dr. Robert Hogg, one of the Vice-Presidents from the commencement of the charity; and also of an able colleague, Mr. W. G. Head, an active supporter of the Fund, and so long associated with the Crystal Palace at Sydenham. Mr. G. H. Cuthbert, of Southgate, has been elected in his stead.

The members of the Executive Committee, who retire by rotation, are Messrs. Assbee, Ballantine, Cannell, Cummins, Gordon, Roupell, and Wynne, all of whom offer themselves for re-election, with the exception of Messrs. Ballantine and Cannell, who retire, Mr. A. Outram and Mr. G. H. Richards being nominated to succeed them. Mr. A. F. Barron is again nominated as Secretary, at the same remuneration.

THE FRIENDLY SUPPER.

This was laid for 6.30 in an adjoining room. Mr. P. C. M. Veitch had been announced to take the chair, but was prevented by illness from doing so. N. N. Sherwood, Esq., therefore acted in that capacity, and a very enjoyable evening was spent.

After the usual loyal toasts had been honoured at the Chairman's invitation Mr. Sherwood gave the toast of the evening—"Continued Success and Prosperity to the Gardeners' Royal Orphan Fund." In the course of an interesting speech he urged upon his audience the advisability of interesting as many gardeners as possible in the "Fund," and assured them of the readiness of the members of the nursery and seed trade to do all that lay in their power to help and further the interests of the same. In referring to the donations that had been made to the charity during the year, he spoke of £31 sent by Mr. M. Todd of Edinburgh, which had been received since the publication of the report, which had therefore not appeared in it. He coupled with the toast the name of Mr. W. Marshall. The latter gentleman suitably responded.

The programme also included toasts to the Chairman from Mr. W. Marshall, and to the Secretary, Mr. A. F. Barron, at the instance of the Chairman.

Dated January 22nd, 1898.

PRUNING ROSES.

EVERYBODY is asking what is to be done about the Roses this season ; and, indeed, it is somewhat difficult to say. Our climate has almost been outdoing itself. "None but himself could be his parallel." Last January is said to need 100 years to show its like, and this month is almost as unseasonably mild. It would be an advantage if one of the authorities—say, any early and a late pruner—would say what they are doing this year, and why.

I have now been released so long from the grave responsibilities of pruning show Roses, that I am rather out of court, and am inclined in this, as many other things, to "follow Nature." The season calls for early pruning—well, then it shall have it. My experience has been that it does not matter very much ; the Roses come into flower much the same time, pruned anywhere between the middle of February and the middle of March. They can hardly help bleeding, I think, somewhat this season.

I have also been adopting the fashion, which now prevails in happy gardens where exhibition blooms are not absolute, of bending over a very big shoot instead of cutting it away. The result is great addition to the quantity, if not in quality of flowers. How such will turn out this season it is hard to imagine. Already with some of mine very nearly all the buds seem to be starting. My rule has always been the last week in February for pruning H.P.'s, and the last week in March for Teas, with H. T.'s possibly between the two. But really this season discounts all preconceptions.—A. C.

[With branches in their natural position the lower buds remain longer dormant than when the stems are bent or pegged down. Is it not desirable to keep the basal buds quiet yet awhile by deferring close pruning, that would force them into growth? We hope to shortly publish further notes on pruning, that may be useful to some readers.]

GARDEN ROSES.

THE fact that Lord Penzance has discontinued the prize that he has for the last three years offered at the Metropolitan Show of the N.R.S. for garden Roses, on the ground of so little interest being taken in them, was suggestive, and instead of damping the ardour of those who wish to encourage their growth should lead to more earnest exertions to extend it. But one or two things have to be taken note of ; those which Lord Penzance wished most to encourage were such as few amateurs, I think, care to take much trouble about. He was anxious that more attention should be paid to the Gallicas, Hybrid Bourbons, and Hybrid Chinas. Now anyone who has seen the stands set up for the prizes for garden Roses knows how few of these appear amongst them, and the truth is they are nearly all out of bloom in the Midlands and South of England before the date of our show. Another reason, I think, is that there are no Roses amongst them, or hardly any, of which we have not as good amongst the H.P.'s, with the advantage that we may get a second bloom from our plants, while in the case of the former we never see one after the flush of bloom in June is over.

We never see, for instance, in our stands of prize blooms such Roses as Juno, Paul Perras, Paul Ricaut, and others, which before the introduction of the Hybrid Perpetual Roses were the joy and pride of our gardens. What grand varieties they are for pot culture! Even now there lingers in one's memory the magnificent plants which Messrs. Paul and Son of Cheshunt and Waltham Cross, and Mr. Turner of Slough, used to bring to the great exhibitions of the Crystal Palace, and which almost took away the breath of the French Rose growers when they saw them at the great exhibition held at South Kensington. It is true they were rather formal in appearance, but they were magnificent examples of cultural skill.

These summer Roses might be comprised under the heads of Provence Roses (under which might be included the Mosses), the Gallicas, Hybrid Chinas, and Hybrid Bourbons, but there is oftentimes a difficulty in accurately fixing the positions of some, so ready are they to hybridise and partake of the characters of the various divisions. There are many delightful variations which became permanent occupants of our gardens. What great favourites, for instance, were the various Moss Roses? Then there was the fine old Cabbage Rose with its delicious perfume, and the favourite of our cottage gardens all through the south of England. Then, again, how dear to some of us are the dwarf and sweet-scented varieties which some way or other were produced amongst them, Rose de Meaux, Spong, Burgundy ; and amongst these summer Roses we also find our best striped Roses. Gloria Mundi or Village Maid is one of the clearest and brightest of these, and though it is often called York and Lancaster, that name properly belongs to quite a different Rose. I remember some years ago when good prizes were offered for a box of York and Lancaster that several stands were exhibited, but not one of them contained the true variety, but all Gloria Mundi. We have had striped Roses among H.P.'s, but I do not care for Pride of Reigate, and Merrie England, a sport from Heinrich Schultheis, has not been sufficiently tried as to its remaining constant in its striped character.

Now it is amongst these summer flowering Roses that we are to look for the old favourites of our gardens which people called "dear old-fashioned Roses," and no attempt seems to have been made except by

Lord Penzance to obtain any improvement amongst them. Moreover, I have gone through a great many Rose gardens, and some where garden Roses were made a feature, but these varieties, with a few exceptions, were conspicuous by their absence. I am writing of course only of amateurs ; some traders may grow them to meet any possible wants of customers, but I rather imagine that the demand is very small. I frequently hear how great is the demand for garden Roses, but it is not for such Roses as these but for small growing Teas and Noisettes, Polyanthas, single Roses, and Hybrid Sweet Briars, that the inquiries are made, and in these classes many additions have been made of late years. This is well, and English gardens will be the richer for their encouragement.

The whole matter resolves itself into this : Is it desirable to encourage the preservation of these summer-flowering Roses? and if so, in what way is encouragement to be given? This can only be, I think, by making a separate class for them, for if the class be for garden Roses it will inevitably come to pass that these will be to a great extent excluded, and the stands filled with the classes which I have mentioned above. Should this question be answered in the affirmative I think it will be desirable that prizes be offered for them—not at the Metropolitan Show, where they are nearly all over, but at the Southern Provincial Show, which will be this year held at Bath, and will be ten days earlier than the Metropolitan Show. I have alluded only to the shows of the N.R.S., because if there be any more to be made in this direction it ought to emanate from that body. I have thrown out these hints for the due consideration of its members, and hope that others who are able to deal more practically with the subject than I am, owing to the smallness of my garden, will give their views on the subject.—D., Deal.

SEASONABLE WORK.

OWING to mild weather and a fair amount of sunshine Roses under glass are coming on rapidly. It is therefore necessary to be on the look out for insect foes, more especially the green fly, which is sure to be in abundance immediately new growth commences. It is not difficult to kill this insect, but even if we apparently kill the whole of those in the house, others soon make their appearance. The secret of success in battling against this foe is to tackle it early, and continue the attack in a mild way. This is far more effectual than waiting for a multitude of insects, and then adopting extreme measures for their destruction. A free use of the syringe, with a very weak insecticide, will have great effect in keeping them down, while it will also stop thrips and red spider. Roses do not approve of a dry and parching atmosphere, nor one that is heavily charged with moisture. They enjoy a midway course between these ; and by using the syringe in the way I have described we give the needed moisture, and check insects at the same time.

I have heard more than one gardener say his Rose house was free of insect foes, but I never yet failed to find some, and often several he was not acquainted with. In my opinion growing Roses—in any quantity, not an individual plant or two—are never absolutely free of insects. But we can keep them within bounds, so that they do very little injury to the plants. And as the strongest measures will not completely eradicate them, while they will most certainly injure our plants, I would earnestly advise that very mild measures be applied more frequently in the way of preventives.

As the plants progress a slight rise in temperature may be given, especially at night. Weak liquid manures are valuable to growing plants, and none more so than the drainings from a cow stall. Artificial manures are good in many cases, but they seldom feed the foliage in the same way as natural manures do. Do not give liquid manure to a very dry plant, and if you use it weak and often it will be of greater help than a strong dose once a week.

A house of Roses growing healthfully and clean is a pleasant sight to anyone, even when the plants are without flowers ; but plants infested with insects or the wood breaking irregularly cannot please. It is necessary to have well-matured wood to start with, a suitable compost, and very steady treatment at first. Where either of these is missing we are sure to find it a difficult matter to secure anything approaching a satisfactory result.

Ventilation needs considerable care and judgment. I would not ventilate at all at this time of the year unless absolutely forced to do so through a spell of bright sunshine after the house was already heated to the desired temperature. A slight damping down of the walls and walks will be found a great help at such times. Where the plants are in pots it is well to go over them, and slightly stir the surface soil once a fortnight. It does not take long to do a good number of plants, and if they are turned round at the same time it is astonishing what progress they make. Besides, when in such close contact with the plant we are able to note if the soil is in proper condition as regards moisture. A plant amongst several others may often be dry or sodden, the fact not being easily discovered when giving water to the bulk. A very little water will keep the surface moist, and only great experience can enable one to be certain from a rapid glance only.

A thoroughly good soaking of liquid manure, rather strong, may now be given to most Roses established in borders, and commencing growth. It is also well to see that young growths of Maréchal Niel, and others upon the roof, do not touch the glass. A sharp frost will freeze them to it, and generally do much damage, often being the main cause of blind or flowerless shoots.

In the open ground we shall soon be busy pruning, and a few notes would seem seasonable. First of all bear in mind what you are pruning for ; whether for a few exhibition blooms, or a quantity of flowers. You cannot have a large number of good exhibition flowers upon the same

plant at the same time. I am not now alluding to such as the so-called garden Roses, which are best fitted for show purposes when grown naturally, but those of the three chief classes, H.P., H.T., and Teas, which we see in such grand form at the best Rose shows.

If you wish for quantity, at the expense of quality, quite double the amount of wood should be left. Most of us prune too early—too much upon a given line, without due regard to the peculiarities of individual varieties, independent of the class or section to which they may belong, and which can only come from long experience. I fear that to go fully into this matter would occupy too much space at present, but may refer to it again: in the meantime pass to another point.

All budded Briars and other Rose stocks, whether standards or dwarfs, should be cut off to within an inch or so of the bud as soon as possible now. Many of ours are already done. This is distinct from pruning. From now onwards, watch for and cut out all eyes which are below the Rose bud, and which would form injurious suckers. It is not too late to plant yet: but, unless under exceptional circumstances, all planting should have been done ere this, seeing what a favourable season we have had. I do not remember a better, nor one so prolonged. Do not be disappointed if, through late ordering, you are supplied with small plants. They are far the best when well ripened and healthy, and more often than not thrive much better than those of double and treble the size. So long as they have a few sound eyes near the base, these suffice. The larger ones are cut down to practically the same level when pruning, and do not, as a rule, have such fibrous and valuable roots.—PRACTICE.

CURRENT TOPICS.

THE MILDNESS OF THE SEASON.

My few remarks on page 601 of your issue of 23rd December last, concerning indications of prospective mildness of the winter, have become of even more interesting import since. It seems there is a clearly established analogy in the weather over a great breadth in Europe, at least since the early autumn. In the corn-growing interior of Russia a considerable amount of drought has wrought havoc to autumn seed beds, and we read since of a light black frost in those regions. Thus, comparatively, the absence of rain or snow over an important extent of latitude correlates with the observations of a retrocession of ice (previously mentioned) as reported from the Arctic by all the returning shipping during the autumn, beyond previous experience. We also read from Bødø in Norway, within the Arctic Circle, under date of 20th January, that sleighing has been possible on only two days this winter. The relative absence of snow, and hence of cold, goes hand in hand with that of rain, and intensifies the possible primary cause for the actually experienced mildness. In trying to reconcile symptoms converging on the general mildness of the European winter with the opposite result that should exist elsewhere, we read recently of a terrific blizzard in the United States having affected half of its enormous area—a possible result of accumulation of Arctic ice in the northern regions of that exposed continent, that is unblest by a mountain barrier across its stupendous breadth to repel Arctic influences. All those interested to look beyond the mere fact of a phenomenal mildness might recognise with me the solution, or part of it, in the condition of things described. It might lead to further useful inquiries. Among messengers of spring I may mention, not having noticed their advent mentioned elsewhere, that I saw several frogs hopping about my garden in January.

CENTAUREA CANDIDISSIMA.

Seeing the remarks (on page 132) as to this plant not being found the easiest to propagate, my old plan of placing cuttings singly in thumbs might be acceptable. The very loosely adhering, delicate rootlets, singular in their being of the frosted tint of the foliage, are easily detached on potting off a batch from a 6-inch pot. Short leafstalks being only allowed of 3 or 4 inches length above the silver sand, is a safeguard against damping off. In the ease of your correspondent there was the drawback of a Box-edging a foot high next to the line of Centaurea and "Geranium" inside, a combination which does not improve the quality of cuttings taken from that shady depth close to the ground level, as necessitated by the habit of the plant. Its supreme effect is undoubted, as no other plant of similar boldness and neatness attains such tint. If I had only a few beds to provide for in a garden, I should not like to be without one having the Centaurea as an edging, with *Coleus Verschaffelti* for the centre. The splendid transparent claret colour produced by a glimpse across the bed, with the sun in opposition, is not easily excelled. I have found it a good plan to place a few spare plants of Centaurea singly 2 feet apart on some spare place in the full sun to provide the best cuttings.

[We have always found isolated plants give the best offsets, and, by the method indicated, have had no difficulty in raising the number of plants required. Plants are easily raised from seed.]

HALL FOR HORTICULTURE.

It was very opportune on the part of the Chairman of the Royal Horticultural Society, Sir Trevor Lawrence, to bestow a graceful thought on this project on the occasion of the annual meeting of this Society. I am afraid, however, the allusion appeared to himself somewhat mirthful rather than meant for business, when he hinted at members doubling their subscriptions towards carrying out the project of the Hall. The flourishing condition of the finances of the Society and the heavily increasing numbers seeking membership might perhaps have furnished an excuse for his frame of mind. All thoughtful members, however, should lay to heart

such a plan as a very small step indeed towards the practical realisation of the object of securing a site, on the Thames Embankment by preference, and magnanimously disposed citizens might yet have a word to say on seeing a serious effort making in the creation of a fund for building the Hall. I ventilated this matter in your issues of 23rd December last and 13th January, on pages 606 and 32 of your publication, and had hoped that some voices might have been raised in favour of supporting such a plan on the part of the various floricultural societies who would agree to this common centre. However, there is always time for "those to be helped who help themselves," and this latter movement, I think, might well be supported by the Council of the R.H.S., who would take any steps they deemed advisable to that end with the least loss of time, and with the best results if done with the necessary emphasis.

The publications issued by the Society under the able conduct of the Rev. W. Wilks, the Secretary, whose own records with other reviews of plant life are swelling into the importance of a small library by themselves, are alone worth that annual guinea mostly subscribed for membership. The annual exhibitions at the Temple flower shows have reached their climax of excellence in this country, and that is saying in the world, and who would not consider the privilege of inspection, from an educational point of view, cheaply bought at another guinea, especially with the Crystal Palace Show thrown in, as well as the Drill Hall meetings of the year? The Show at the Temple has become the true national arena of our great horticulturists, and no British grower aiming at leadership likes to be unrepresented there. These interesting meetings at the Drill Hall, of which there are eighteen annually, are becoming very fair flower shows in themselves, and they would be surely doubled or trebled within a few years from entering upon enlarged premises in the future Hall of Horticulture.

Large nurserymen should not be reluctant to admit their increased prospects by such extension. The fortnightly displays would become immeasurably more important if placed prominently on the Thames Embankment, especially with music added for an hour in the afternoon. The floricultural societies and a little music might assist each other effectually. A great impetus would be given to horticulture by the change suggested. A capacious hall is actually needed by the R.H.S. by reason of the increasing membership and the increased demand for space at the meetings.

Strike the iron while it is hot, and while favourable words are fresh from a multitude of articles that have appeared in print. There is the Chrysanthemum Society thirsting for fresh quarters. All that is wanted is the clear intimation of such a centre to become a reality, for an overwhelming number of members of that Society to be ready to embrace the opportunity. Of course it would only be fair that all the Societies ready to join should adopt the same plan as suggested, for the R.H.S. to address a formal proposal to their members to double their subscriptions for the said purpose. About £5000 should be raised by the combined Societies. When this is done there seems little doubt that wealthy friends of the highest and purest cultural embodiment of earthly refinement will not allow the attainment of our most desirable project to languish.

PLANTS AND GROUPING.

I have attempted to protest against scentless Roses and coarse developments, mainly for size only, in such favourite plants as Chrysanthemums, double tuberous Begonias, and similar forms, and should include monstrous Caladiums as exhibited of late years as a direction of taste to be deprecated. It may, therefore, not be amiss to allude from a similar point of view to the class of plants of so much attraction when in flower, and of so much intrinsic value—viz., Orchids. Nothing seems, perhaps, more justified than the admission that where for the gratification of our senses so much extreme beauty as Orchids in flower possess is produced, there should be, from the eternal laws of an even balance in all things, an equilibrium result from their retreat when out of flower into a state of most grotesque ugliness. Its inherent unmitigated dejection must depress our spirits as would the sight of a fleet of derelicts.

But as all horticulture is only another expression for a judicious assistance of Nature, why should not this opprobrium attaching during three parts of their existence be removed? A mere trifle is needed, perhaps only to be thought of in some cases, in order to be made available. Natural associations will do it. Even in their flowering state Orchids would be much more attractive in more natural surroundings than are provided by a group of them unassisted, or too scantily assisted, by any neutral feature to be provided in accordance with the particular flowering habit of each class. I am referring only to plants as grown in private establishments.

Plants to be used for association should be very accommodating and maintained in their perfect condition under treatment as required by any particular class of Orchids. When out of flower Orchid plants would retreat out of notice among characteristic natural surroundings and associations of continuous attractive features. Moderate-sized foliage plants, especially graceful kinds such as *Cocos Weddelliana* and *Geonoma gracilis* among Palms, or *Aralias*, *Eulalia japonica variegata* mixed with a few bolder features like *Begonia Rex*, *Marantas*, and *Dracenas*, or with Ferns and *Selaginellas*, an occasional re-grouping would provide an opportunity for the display of taste by gardeners, deficiencies in which might be thus improved upon.

As to Ferns and *Selaginellas*, conventional pots should be used in a minority, although they would do for *Neottopteris* and *Lomarias*, not to forget *Adiantums* and similarly constituted classes. But I should like to draw attention principally in this connection to *Davallias* lending themselves for considerable effect, but not in pots in the usual way. From

bundles of Spanish cork Oak bark should be selected, such, not infrequent, growths that form a complete length of stem (minus the timber). If these lengths, of about 4 to 8 inches in diameter, were inserted in pots several inches wider, there would be room near the edge of the pot for rooted portions of *Davallias* that would within a few years cover naturally the cork, and with unusual effect if judiciously guided and tied round with raffia until rooted to the cork. I recommend this style of easy training for much more general use. It should be made a feature in every greenhouse and stove, when *Davallias* would promptly become favourites, for these plants thus formed would be a most desirable change among table decorations. The most perfect distribution of fronds thus produced can hardly be appreciated unless seen, and that the excellence of the picture should be so striking a feature is, I think, mostly unsuspected.

Hardly anyone seeing *Davallias* crouching on level surfaces of pots or pans, or bundled up in suspended baskets, thickly rooted, with hardly one frond seen to advantage, because on all sides overlapped, can conceive what a revelation a perfectly grown short cone of about 18 to 24 inches high would be. A single basket of *Davallia Tyermanni* appeared among a group of plants at the last Drill Hall meeting. The basket was crowded with roots and fronds, and all effect was lost. If such a mass were pulled in pieces and divided among, say, four or five 8-inch pots, with a complete piece of cork branch inserted, and carefully trained for a year or two, the operator would be surprised at the difference. The sight of such objects of beauty would suffice to sell them promptly, whereas nobody would look at the basket.

I select this variety, *D. Tyermanni*, in order to accentuate that its effect is the most striking of all *Davallias* (the otherwise popular *Hare's Foot*), mostly applied to *D. canariensis*, from the contrast in tints between the fronds, bark, and rhizomes. *D. Mariesi* would even cover the bark more promptly, and also the lovely *D. fijiensis* would mark a further phase in public favour were it only treated with the respect and patience to arrive at the results pointed out. There are some three dozen varieties of *Davallias* to select from, but other classes would do, including particularly our common hardy *Polypody*, a class name, covering also the striking *Polypodium appendiculare*, with its dark rich veins on every portion of its fronds, which would be something to look at for Orchid lovers, and to hide their derelicts. I need hardly insist on a change through *Adiantums*, but should like to name *Farleyense* and *Williamsi*, the latter the most perfectly formed frond among *Adiantums*, its attraction consisting in its lightness, unconfused.

As the grouping of plants usually seen at the Drill Hall there seems little in it to recommend the style. You usually see a confused mass of plants, one jostling the other, of nearly equal height, and hardly one of them showing the true merits of any one plant. I should like to see an arrangement of common *Selaginella* established in pans and well developed for the groundwork, with spaces provided for specially attractive foliage or other plants, allowing each to have justice done it and seen thoroughly. The effect of such a group on the *Selaginella* would probably be appreciated on all sides. Of course the *Selaginella* would have to be grown consistently so as to show a natural even surface, and the plants interposed to show no intrusive pots.—H. H. R., *Forest Hill*.

THE YOUNG GARDENERS' DOMAIN.

THE TUBEROUS BEGONIA.

In a previous article I treated on the Begonia for bedding purposes, and will now give a few notes on the culture in pots. Where tubers are in stock they should be examined forthwith, and if any have started into growth they must be potted at once, using good fibrous loam and leaf soil in equal parts, with plenty of sand. The size of pots should be determined by considering the after treatment and the size of the tubers. I prefer to pot them at once in the pots in which they are to flower, the largest tubers being grown in 9-inch pots, and by this method they give entire satisfaction. More than usual care must be given to drainage, for when growing freely they will require abundance of water, which must pass away quickly to prevent the soil getting sour.

A third of the remaining tubers ought to be laid in seed boxes full of leaf mould, and kept moist in an intermediate house until they have become well rooted and made an inch or more of growth. The large tubers can be divided, leaving a growth to each half and dressing the wounds with powdered charcoal. Keep them close and shaded after potting until growing freely, when more air will be required. It is a great mistake to force the Begonia unduly at any period, especially during the early stages of growth. Neat stakes to support the growths and blooms will be necessary. They are charming when arranged with *Adiantum cuneatum*, and the temperature and shade required for the latter suits them admirably. The remaining tubers should be grown in successions, and with good treatment they will be gay with flowers until late in the autumn.

Clear soot water alternately with artificial manures is beneficial to them when the pots are full of roots, but care should be taken not to give either manures too strong, the roots being easily injured.—NIL DESPERANDUM.

REJUVENATION OF OLD PEAR TREES ON WALLS.

THE season for nailing is almost over as regards Pears, and soon those on walls will be in bloom. In most gardens there are to be found some old trees which apparently have had their day, and although they do not look worn out their crops are unsatisfactory, the fruit inclined to be undersized and gritty, not worth putting upon the dessert table. Many

of these trees may be rejuvenated and turned to good account in a short time by cutting back the branches close to the stem, and allowing an entirely fresh start to be made. First of all, it is advisable to attend to the roots. If in old gravelly soil which has not had a chance of being manured and worked properly, they should be subjected to a good root-pruning and put in suitable loam, taking care to add a fair amount of wood ash and lime rubble, with decayed cow manure amongst them.

This operation should take place a season before the one in which the branches are to be cut back, as it gives the tree a chance to establish itself firmly again, and be ready for prompt root action when most necessary. Perhaps the month of February is the best time to take off the branches, and this should be done properly, no half measures. Cut back right to the stem until it resembles a clean bare post, and leave no stumps or snags. At this stage of the proceeding opportunity should be taken to cleanse it properly if at all troubled with insects or scale, and I know of no more reliable compost for the purpose than slaked quicklime and soot mixed, and applied with a brush into all crevices of the bark and all over the bole.

The buds will push out plentifully, three or four from each old branch base, and then it is simply a matter of taking the best in the nearest position for training, removing the others. In two or three seasons the trees will be fairly started again, clean and strong, ready to bear first-rate fruit as a young tree. The varieties I have seen most successfully treated

Fig. 27.

Fig. 28.

WEST'S PATENT POT RIM. (See page 164.)

by the above method were Marie Louise and Easter Beurré. Both bore good, clean fruit the third season, and were upwards of twenty-four years old when the work of rejuvenation commenced.—R. A. ANDERSON, *Alnwick Castle Gardens*.

COVERING WALLS AND PILLARS.

AS we travel about visiting places and gardens one cannot help noticing a number of bare walls, pillars and outhouses, which might be made objects of beauty by the aid of flowering or evergreen climbing plants.

IVY will only be given a passing word, as it is so familiar to everybody that it needs no comment from me. It will thrive almost anywhere, and being evergreen, always looks well, especially the variegated forms. To keep it in trim it should be cut back close to the wall each year in the month of March or April.

AMPELOPSIS VEITCHI is an excellent hardy climber, and when once planted will require very little attention, as by nature it clings tightly to the wall and requires considerable force to detach it when necessary. It grows quickly, and for autumnal beauty is, in my opinion, scarcely equalled by anything we have; certainly not excelled. The leaves of this variety are much sought after for dessert dishes and table decoration.

AMPELOPSIS HEDERACEA is a close ally of the foregoing, differing from it in habit, also size and shape of leaf. It is best adapted for covering lofty pillars and verandahs. The main branches should be secured by means of wire trellises attached to the pillars or to the verandah by the use of nails and shreds, pruning being done much on the same lines as that practised on the Grape Vine.

WISTARIA SINENSIS is a grand deciduous tree, and produces its racemes of sweet-scented, pale blue flowers in the months of April and May in the south of England, and occasionally flowering again during August. The white variety is very charming. Pruning may be done as with *Ampelopsis hederacea*.

ROSES are excellent for our purpose, and their fragrance is always refreshing after the toil of a hot summer's day. That grand old Rose Gloire de Dijon must still be included in a good list, although it is apt to become bare towards the base as it increases in age. Banksian Roses are very attractive, and should be in every southern garden. Other excellent and well-tried varieties are W. A. Richardson, Rêve d'Or, Boule d'Or, and L'Idéal.

CLEMATISES are excellent climbers and bloom profusely. Two plants of the Jackmanni section, alba and Duke of Edinburgh, adorned the verandah of a vicarage I am acquainted with, and the vicar's wife attended to them herself with fostering care, the gardener not being allowed to touch them. Clematis indivisa lobata is a deciduous climber, and produces its flowers on the wood of the previous season's growth.

CRATÆGUS PYRACANTHA is an evergreen hardy shrub, and produces large bunches of bright red berries in midwinter; it is, in fact, one of the best berried plants for winter work that we possess. It requires support in the shape of nails and shreds neatly applied.

COTONEASTER MICROPHYLLA is even better than the foregoing for thickly covering a wall. It is perfectly hardy and produces small white flowers singly during summer, followed by small red fruits in the autumn, and remaining through the winter. Of these berries the birds are very fond, especially the yellowhammer. The plant requires support like the foregoing.

LATHYRUS.—Several species of this, the Pea family, are useful for pillars, but may be objectionable to some on account of their habit of dying down to the ground in the autumn.

JASMINUMS are good climbers. The yellow *J. nudiflorum* is in bloom with us now, and is quite attractive at this dull season.

PIRUS.—Amongst these may well be included as wall plants *P. japonica*; it is very beautiful just now with its masses of bright red flowers. Habit deciduous.

SWAINSONIA GALEGIFOLIA is good for pillars, but is deciduous. It flowers profusely during the summer months, the colour of the flowers being purple red.

MAGNOLIAS are excellent for large walls. *M. grandiflora* is an evergreen; flowers creamy white, very sweet scented, and about a foot in diameter. *M. Soulangeana* is a deciduous hybrid, and produces purple white flowers in great profusion during April.

CEANOTHUS.—*C. azureus* bears profusely large racemes of light blue flowers, which not only look beautiful on the plant, but are useful also for cutting purposes. This variety being only half-hardy, should be assigned a position on a low south wall. It requires nailing as does a Rose.

HONEYSUCKLES ought not to be forgotten, the Scarlet Trumpet (*Lonicera sempervirens*) being especially good and floriferous. All the above may be purchased from a good nurseryman at any time of the year in pots, and anyone contemplating planting should do the work at once. They will succeed well in fibrous loam, with a fourth part of good leaf mould added.—T. P.

[Is *Swainsonia galegifolia* generally accepted as hardy? It is a recognised greenhouse or conservatory plant, and *Clematis indivisa* is usually grown under glass, producing a charming effect in conservatories.]

HARDY FRUIT GARDEN.

Improving Fruit Trees.—Fruit trees are always capable of improvement when the branches are crowded together, unduly contorted in shape, or grow into each other from opposite directions. The results following negligence in this respect are to be seen in fruitless branches, loss of vigour, and ultimately accumulations of worn out spurs and dead wood.

Standard Trees.—To effect permanent improvement with standard fruit trees, the first essential is that each individual tree has ample space allowed it all round. It should stand at least 20 feet apart from other standard trees, no matter what its age or size. Fully grown trees require all the air, light, and space possible, and young trees in the process of development need the above conditions just the same to assist their extension. This is frequently lost sight of. Trees are planted closer than they ought to be in the first instance, and are not allowed to be removed in time for preventing their injuring one another. This can be rectified to some extent, but never so well as when the trees are beginning to touch. The next step is to thin out the branches. Do not hesitate to allow each plenty of room, but where there is much pruning required it may not be wise to carry it all out in one season. Some branches might be removed in summer and the rest the following winter, a preliminary clearance being carried out now as a commencement. Thinning out, not shortening, is the principle to follow in pruning standards.

Pyramids and Bushes.—The trees individually are not so frequently crowded, but the branches are often found to be inconveniently numerous. When this is the case the number ought by all means to be judiciously reduced. The continual cutting back of wood to form spurs causes these to be crowded and elongated, hence it is desirable that some reduction and thinning of them should take place. Weakly spurs are best dispensed with if possible. They produce leaves, which may shade those attached to better spurs. Dead growths and spurs are usually the result of overcrowding, and in renovating trees every portion ought to be cut out. Furcation of the branches may cause crowding. When this is so, cut out the least desirable, having, as far as possible, each branch a simple cordon.

Wall Trees.—The tendency to crowd the branches of wall fruit trees when young leads to disastrous results later. The branches of Apples, Pears, Plums, and Cherries which are spur-pruned ought not to be less than a foot apart. Some that grow strongly may be wider apart, especially on low walls. The most vigorous growth takes place on the upper branches, and strict attention must be given not to allow them to become unduly furnished with long spurs, that will shade those below them.

Furnishing Fruit Walls.—The most suitable fruit trees for furnishing walls of various aspects is often a matter of importance. Apricots, Peaches and Nectarines ought to have the best positions on south walls which are high enough to permit of free extension. South aspects being the sunniest and warmest enables the fruit to be brought to perfection, as well as thoroughly ripening the wood. Choice Apples, Pears and Plums may also have similar aspects, other varieties of these fruits having a western wall. East walls may also be devoted to hardy Plums, Pears, cordon Gooseberries and Red Currants, while north walls may be planted with Morello Cherries, cordon Gooseberries, and Currants.

Pruning Gooseberries.—When Gooseberry pruning has been left over on account of birds attacking the buds the bushes ought now to be dealt with. The severe pruning practised by some is not advisable where much damage is done by birds. Fruit is produced freely on young wood of the previous year, therefore all that is necessary is to leave a fair amount of the best placed shoots all over the trees. Shoots which it is necessary to cut out situated on the older branches may be shortened back to a few buds forming short fruit spurs. Cut out growths descending to the ground, or any that crowd or destroy the shape of trees. Dustings of soot or lime will prevent the buds remaining being attacked until they break into growth, when they are safe.

Pruning Currants.—Red and White Currants should also be pruned. Like Gooseberries, they suffer from bird attacks if not protected. With these Currants spur-pruning is a necessity, each main branch having all the side shoots shortened closely back to the small spur growths or buds clustered at the base, cutting to within half an inch of the origin of each shoot. Should the leading branch require to be extended in length the shoot forming the leader must be shortened to a length of 6 to 9 inches. Adopt the same plan in the case of young trees, thus gradually extending the branches to their desired length. Strong growths near the base may be utilised, if necessary, for forming new branches to take the place of any worn out.

The pruning of Black Currants is not usually deferred, as the buds are not so subject to damage. Bushes, however, which do need pruning now are best thinned out, leaving vigorous young growths for furnishing and forming shapely bushes, and to produce fruit.

FRUIT FORCING.

Pines.—*Plants Starting into Fruit*.—Those selected about the beginning of last December, and started by an advanced temperature and an increase of moisture, will now be showing fruit, when the temperature may be maintained at 65° to 70° at night, and 75° to 80° in the daytime under favourable circumstances, ventilating at 80°, allowing an advance to 85° or 90°, and closing so as to maintain that heat from sun influence as much as possible. The plants will require more water at the roots, examining the stock once a week, as with increased light and heat the need for water will be correspondingly greater. Recently started plants to follow those already named should have a night temperature of 65° to 70° by day artificially, which will be sufficient for them for some time longer.

Starting Suckers.—These will have to be started at the commencement of March to give a succession of fruit from next December onwards; therefore, attend to the preparation of the soil for potting, and a fermenting bed in some close structure to generate and maintain a bottom heat of 85° to 95° near the surface, and with means of maintaining a temperature 55° to 65° by fire heat in the atmosphere with regularity.

Vines.—*Early Forced in Pots*.—The Vines must not sustain any check either through dryness at the roots or in the atmosphere. If the roots cannot have the run of fermenting material, place strips of zinc 3 or 4 inches deep round the top of the pots, inserting them just within the rim, and top-dress with rich turfy loam and decayed manure in equal parts, intermixed with a handful of superphosphate to each bushel of loam and decayed manure in equal parts; but with the pots plunged to the rim in fermenting material, strips of turf about 3 inches thick should be laid over the rim so as to form the necessary dish. Keep the Vines well watered with liquid manure a few degrees warmer than the mean of the house, also have the plunging material moist, especially when the roots are allowed to find their way into it from the pots, plenty of active feeders being essential to well-filled berries. Do not, however, keep the soil sodden, but allow it to become fairly dry, then afford a plentiful supply.

To encourage the swelling of the berries keep the laterals below the fruit somewhat closely pinched, but allow those above the bunches more liberty, avoiding overcrowding with foliage that cannot have full exposure to light. Also be careful in thinning the berries and in ventilating, taking care not to brush the Grapes with the hand, and to avoid cold currents, as both cause "rust," hardening the epidermis, so that the berries do not afterwards swell freely, and in some cases cracking results. Ventilate early in the day, affording a little air at 70°, increasing it with the sun heat to 85°, and closing early so as to secure a temperature of 85° to 90°. Keep a sharp look out for red spider, and let the first specks on the leaves be promptly sponged with weak softsoap and water. An ammoniated atmosphere has a good effect on red spider, the best being that of stable drainings, diluted, when neat, with about five parts water, using about a gallon to 10 square yards of paths and walls. Painting the hot-water pipes with sulphur brought to the consistency of thin cream with skim milk is an antidote to red spider and mildew, but the pipes must only be lightly coated, and not heated much over 170°.

Early Forced Planted-out Vines.—Houses closed in November, and the Vines started early in December, will need to have the berries thinned as soon as set, or not later than when it can be seen which have been properly fertilised by their taking the lead in swelling. Tolerate no

surplus bunches, remove badly set and ill-shaped clusters, seeking a full crop of compact, good shaped, well furnished bunches, properly swelled and perfect in colour and finish, which are more profitable and much more creditable than an enormous crop of large loose clusters of unevenly swelled berries, red in colour, with a large percentage shanked. Allow laterals to extend beyond the fruits where there is room for exposure to light, but in no case must laterals be encouraged to the prejudice of the principal leaves. Attend to stopping frequently, for the alternating accelerations and checks to root action, consequent on encouraging the laterals and then removing them by armfuls, are attended with the worst consequences to foliage and fruit.

Afford a thorough supply of liquid manure to the inside border at intervals as required to keep the soil in a properly moist—never soddened—condition, and mulch with an inch of sweetened horse droppings or rather lumpy well decayed manure. Fresh horse droppings give off too much ammonia, this injuring the foliage when too powerful, especially when the house is kept close in dull periods. Maintain a night temperature of 60° to 65°, 70° to 75° by day, ventilating from 70°, keeping through the day at 80° to 85° with sun, closing so as to maintain this heat, or even 5° more, until well into the afternoon, and well damping the house. Avoid syringing the foliage and fruit, as however clear and soft the water may be, there is danger of sediment; indeed, all may appear clear until the Grapes begin to finish, then the purple or golden hue stained with white is a serious blemish.

Vines in Flower.—The temperature must not be less than 60° to 65° at night and 70° to 75° by day. Lessen or discontinue the syringing, though moderate moisture is desirable for the benefit of the foliage, preventing condensation of moisture by a little ventilation constantly, taking care not to cause a draught. Shy-setting varieties require careful fertilisation, all varieties well repaying the labour by producing finer bunches of evenly formed berries. Afford Muscats in flower a night temperature of 65° to 70°, and 75° to 80° by day; if the bunches are numerous a better set will be secured by the removal of the surplus ones before they bloom. Duplicates only take support from those which are ultimately left for the crop.

Thinning Grapes.—Keep this operation well in hand, thinning Black Hamburgs and other free-setting varieties as soon as possible after flowering; but the shy-setting Muscats and others should be left until the properly fertilised berries can be distinguished. Sufficient berries should be taken out to allow of those left attaining their full size without wedging or crushing, retaining enough to prevent the bunches falling out of shape when cut and laid upon the dish.

Succession Houses.—Attend to disbudding as soon as the best shows for fruit can be discerned, proceeding gradually. Stopping may take place one, two, three, or four joints beyond the show of fruit as the space admits, but the leaves beyond the fruit having exposure to light, the more certain is it of being well supported. If the space is limited stop at the second joint, or even one beyond the bunch, but where space admits stop the growths at the third or fourth joint beyond the bunch, and then allow the laterals to extend until the available space is covered with an even spread of leaves, then keep them closely stopped. Tie the growths down before they touch the glass; bring them down carefully, as the growths of vigorous Vines are liable to snap. Allow plenty of room in the ligatures for the swelling of the shoots. When the bunches show increase the temperature to 55° to 60° at night, 65° by day artificially, 70° to 75° from sun heat, and advance to 80° or 85° from that source, especially after closing.

THE BEE-KEEPER.

STRAW SKEPS.

ALTHOUGH the moveable frame hive has made great headway throughout the country, there are many bee-keepers who adhere to the hive of their forefathers, and will not discard the straw skep in favour of the more modern frame hive. Why this should be the case it is somewhat difficult to say, as one may show them how easily the bees are manipulated in the modern hive and the surplus honey removed without injuring or destroying the bees. Still they will work on the same lines as before, with the exception of destroying the bees, which was invariably done not many years ago.

Bearing in mind the fact that there are more bees kept in straw skeps throughout the country than some people imagine, it may be interesting to them to know the various means at their command of obtaining a surplus. In the first place, it is as well to remember that it is much easier to obtain a large surplus from a frame hive than it is from an ordinary straw skep. This has been the experience of all who have given both systems a fair trial—not only in the extra weight obtained, but also in the superior quality. If, however, close attention is paid to straw skeps, and the bees receive extra room when required, it is surprising the large amount of honey that may be obtained from a strong colony in a favourable season. If a good harvest of honey is expected swarming must not be encouraged, unless the chief source from which the honey is obtained is the Heather. In that case a limited number may be allowed to swarm with advantage, as the aim of bee-keepers should be to have their hives as full as possible of bees when the honey flow comes.

OBTAINING A SURPLUS FROM SKEPS.

If the bulk of the honey is taken from field Beans and white Clover, it is impossible to obtain a satisfactory surplus from stocks that are allowed to swarm indiscriminately, and when once they have the swarming fever, no after management will prevent them. Our experience with first swarms is, they appear to work much harder when placed in their new home, in comparison with those that have not swarmed. But as there would be only a given number of bees in the swarm when they left their parent hive, there would be no increase in numbers for three weeks at the earliest, while a fortnight at the least would have to elapse before the newly hatched bees would be of any use as honey gatherers. By that time many of the old bees would have died off, and unless the swarm were an extra early one, the chances are that the best part of the honey season would be over before they were in a condition to gather and store a surplus. A stock that has not swarmed will continue to increase at a rapid rate. The hundreds of bees that are hatched daily will soon cause the hive to become crowded, and if ample room is provided for the fast increasing colony, the bees will work quite as freely as a first swarm.

A stock treated in this manner will be in good condition for storing a surplus should the weather be favourable when the honey can be obtained. Extra space may be provided for the bees by placing an eke about 4 inches or more in depth under the skep. This may be made out of an old skep the same size as the one under which it is to be placed, and the bees will at once commence to build their combs to within a short distance of the floor board. This should allow sufficient space for the bees in an ordinary skep. If more room is needed, it must be given at the top of the skep, as by this time honey will probably be coming in freely.

SUPERS ON SKEPS.

It is as easy to obtain well-finished sections of comb honey from straw skeps as from the most elaborate frame hive. Some of the best finished sections we have ever seen were worked on the top of a straw skep. All that is necessary is to prepare a crate of sections in the usual manner. The crate containing the sections should be placed inside a box slightly larger, so that there is sufficient space round the sides for packing with some warm material, which will be of great advantage in conserving the warmth. The bottom of the box must have a hole to correspond with the one on the top of the skep. The bees will then be able to pass from one to the other. Care must be taken in placing the box containing the sections on the skep that there is no escape of heat, and there need be no difficulty in this respect with a flat topped skep, as a ring of some warm material may be placed under the box. If the skep is dome-shaped it is better to make a platform of clay, or something similar, on which to place the box, so that it may be quite level. The whole must be covered up warm, and due precaution taken to prevent the interior becoming saturated.

Bell-glasses of various forms can be used as supers, but are not recommended if quantity is required. These may be fixed on a level stage similar to the crate of sections. An empty straw skep, in which there have been placed a few pieces of guide comb, also makes a good super; but in this case it is advisable to place a piece of queen excluder zinc over the hole on the top of the hive, or the queen will fill it with brood, and little surplus will be stored.—AN ENGLISH BEE-KEEPER.

SIZE OF HIVES.

ON page 113 "An English Bee-keeper" says, "The standard frame is now extensively used, and before condemning it in favour of another size, it is as well if we study the question and see where the difference is. This I venture to say 'G. H.' has not done, as he recommends a hive holding twelve frames, 20 inches by 8½ inches, which is really much smaller than the standard frame hive as advocated in these pages." I may as well undeceive "An English Bee-keeper." I have studied the question well. I knew the method, and practised doubling years ago, when in my teens. But as yet I cannot see the force of "An English Bee-keeper's" reasoning. The arithmetic propounded is not a fair comparison. In the first place we have a hive to take nineteen standard frames, 14 inches by 8½, giving 4522 inches of surface. Next we have twelve frames, 20 inches by 8½ inches, giving 4080 inches of surface, a difference in favour of the former of 442 inches of storage. This may look all right just as it stands, but it will not bear the searchlight.

Let us look at the hive advocated by "An English Bee-keeper." There are ten frames for brood, that is the hive proper, giving 2380 inches of comb surface for the brood nest. Now, when doubling takes place, another hive the same size is placed on the top, which may be termed a super. Excluder zinc is placed between the two hives, and converts them into hive and super respectively. Again, if the hive is not strong enough bees and combs are taken from another stock to make it so. Can the yield of such a hive be called the produce of one stock? Certainly not, for we have the progeny of two queens at work. Moreover, it is only a hive with ten standard frames, with a super of nine frames on, according to "An English Bee-keeper's" own showing.

Let us take a glance at the larger hive; twelve frames 20 inches by 8½ gives 4080 inches of comb surface. In conjunction with these hives,

we use two supers holding ten frames each 20 inches by 5½. We use ten frames in the supers for the same reason given as "An English Bee-keeper," and it is an excellent practice. I find wide combs much easier to extract. So, instead of having 4080 inches of comb surface, we have 6280, changing the minority of 442 into a majority of 1758 inches. Now, I ask in all fairness, Which is the larger hive? "An English Bee-keeper" has gone away from the question altogether, as it was not the amount of storage room for the surplus honey, which can always be provided for. The question first asked, and which has not been satisfactorily answered, was, "Has a queen room for her egg-laying power in the height of the season, when she is capable of laying from 3000 to 4000 eggs per day?"

HOW MANY EGGS A QUEEN WILL LAY.

Has not "An English Bee-keeper" told us at certain times a queen will lay at least 3000 eggs per day, implying that she will lay more? But where does she lay them? Let us see. There are ten standard frames in the brood nest, there are 54,000 cells at most on ten standard frames. If the queen laid 3000 eggs per day she would fill all of them in eighteen days. But the queen has no such room for her laying power, as we must take off two frames for stores and pollen at the very least, and this would leave the queen room to lay little over 2000 eggs per day for twenty days.

DOUBLING HIVES.

Good results can be had from doubling; this I proved years ago, and practise it occasionally now. My objection to doubling is, that I do not like honey taken from old combs from which successive generations of bees have been hatched. To my palate, honey has the richest aroma that is taken from virgin combs, or from combs that have not contained brood. Is not honey an absorbent, and matter of an unpleasant nature imparted to it with old brood combs? Let anyone try for himself honey taken from combs of spotless whiteness, and honey taken from old black brood combs, compare the two and draw their own conclusions.—GEORGE HOWDENSHERE.

LARGE FRAMES.

"WARWICK" has decided to try the large hives, and while thanking George Howdenshere for particulars already given, will greatly appreciate the correct measurements for frames and hives, so kindly offered on page 136.

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **S. Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Weed Killers (B. S. K.).—It is impossible for us to say which is the "best" of all weed killers, and thus, in effect, stamp all others as relatively inferior. As a matter of fact we have not tried them all, but those that we have tried answered their purpose well. Procure price lists and testimonials from advertisers of the articles, and let them guide you to a decision.

Lachnanthes tinctoria (Alpha).—We are not aware that this plant is a recognised remedy for consumption. It is a native of North America, and known as the Red-root. It belongs to the order *Hæmodoraceæ*, and grows in or near ponds and ditches in America as an herbaceous perennial, producing sword shaped leaves and a dense cyme of yellow flowers. We do not know that plants are obtainable either in a dried or growing state in this country. They are not credited with the possession of medicinal properties, but the roots have been used in America for dyeing, in the same way as Madder—the root of *Rubia tinctorum*.

Newly Imported Dendrobium nobile (W. T. G.).—If the young shoots in your plants of *D. nobile* are producing roots, and you have the convenience of a warm close house, you may take them off now, but they are in most cases better left on the plants for one season. The fact of the plants being "covered" with the shoots seems to point to the fact that few flowers will be produced, so that you have nothing to lose by putting the plants in a brisk heat, with plenty of moisture, and getting a good long season's growth for them. Then next spring you may cut the old stems with the young shoots out entirely, and put as many as you like into each pot. Or they may be placed singly in small pots, but the former is the quickest way to obtain good specimens.

Pentstemons with Blue Flowers (M. D.).—The following have blue flowers. Seeds can be obtained from Mr. W. Thompson, 34 and 36, Tavern Street, Ipswich. *P. confertiflorus*, *syns. confertus* and *procerus*, *P. cyananthus* var. *Brandegei*, *P. glaber*, *P. heterophyllus*, *P. Jeffreyanus*, *P. ovatus*, *P. secundiflorus*, *P. speciosus*, *P. cœruleus*, *P. Scouleri*. Of these *P. confertiflorus*, *P. glaber*, and *P. cyananthus* var. *Brandegei*, which is considered by botanists only a variety of *glaber*, are the hardiest.

Grapes in Heated Orchard House (W. Berks.).—As you have Black Hamburgh, Madresfield Court, Foster's Seedling, and Royal Muscadine in another house, and require two varieties to follow these, the selection is left to late varieties, which, as a rule, require good heat and a long time to ripen the fruit properly for keeping well. Under the conditions you name we think Black Alicante, a strong growing variety, very fruitful, always setting and colouring well; also White Tokay, an old and little grown variety, that bears fruit freely and ripens well with a little heat in September, likely to succeed under the conditions you name, both being the better with a little heat at starting and when ripening. If the soil is light the chances of success will be more certain.

Lawn Smothered with Daisies (Subscriber).—We once saw a lawn more Daisies than grass completely cured by a dressing of the following mixture:—Sulphate of ammonia, eight parts or lbs.; kainit, five parts or lbs.; bone superphosphate, four parts or lbs.; and sodium silicate, three parts or lbs., mixed, using 6 to 7 ozs. per square yard, 14 lbs. per rod, 1 ton per acre. The dressing was given in the early spring, with a prospect of fair weather, the manure simply burning the hearts out of the Daisies, and making the grass look very sickly for a time, but it grew soon afterwards, and made a splendid lawn. The surface was roughed with an iron rake in April, and ¼ lb. of finest grass seeds sown per rod, rolling down. If light land use nitrate of soda instead of sulphate of ammonia, and as your case may not be so bad as that we experienced, try the effect of half dose on a part at the first, and be guided by results, always choosing fine weather, so that the salts may act on the crowns of the Daisies.

Grubs from Herbaceous Border (F. G. S.).—The "grubs" found in digging one of the herbaceous borders are the caterpillars of the small or "garden" swift moth, *Hepialus lupulinus*, which in the larval state live on the roots of a great variety of plants, chiefly herbaceous, but we have found the caterpillars on Celery, Lettuce, Parsnip, Potato, Strawberry, and even grass roots. They are to be found during the autumn, winter, and spring. At the latter time they turn to chrysalids in an earthen cell in the ground, remaining about a month in the pupa state, and then emerge as moths. Perhaps the best means of getting at these pests is to use a little mustard dross, about half an ounce per square yard, sprinkling it on with a dredger or bellows distributing apparatus during fair weather, and with a prospect of its continuance for some days. This we find to act well on surface caterpillars and other ground pests, but only when it is applied when they are active. By digging the ground on dry days several may be exposed, secured, and an infinitely greater number prevented.

Rust on Sweet Williams (W. J.).—The very fine pustules on the under side of the leaves are fruiting bodies of the caryophyllaceous plant rust fungus, *Puccinia lychnidearum*, in the most healthy and luxuriant condition. The Sweet Williams were also healthy, not unduly vigorous, but much disfigured by the large blotches on the leaves. The disease is a very disastrous one, as the mycelium of the fungus strikes deep and wide in the tissues of the leaves, and causes depressed spots on the upper side of them. The spots change to whitish blotches, and ultimately brown, then fall away, and leave holes or greatly disfiguring parts. Sometimes the pustules are very closely together, but not often confluent, or run into each other, as in the *Chrysanthemum* rust, but the blotches are then much larger, and the plants have a sorry appearance. You need not be alarmed about its spreading to the *Chrysanthemums*. We have numbers of spores of the *Chrysanthemum* leaf-rust fungus, all more or less warted, whilst those of the Sweet William rust fungus are quite smooth. Use the copper sulphate powder preparations, or spray with sulphide of potassium solution, half-ounce to a gallon of water, letting the powder or solution reach the under side of the leaves.—G. A.

Sowing Seeds of Alpines (Armitage).—If a frame or cold greenhouse is at command your seeds should be sown in 5-inch or 6-inch pots. Fill the pots half full of drainage. Prepare a compost of good light soil with about one-third of sharp sand and a little leaf mould. Pass this through a coarse sieve. Place a little of the rougher soil remaining in the sieve over the drainage, and fill the pot with the finer earth until it is about half an inch below the rim. Press this firmly with a flat piece of wood and then sow the seed, which should also be pressed into the soil. Cover the seeds with finely sifted soil, and press this down also. The soil must not be wet, but only slightly damp. Cover the seeds slightly, just so as to prevent any being seen. In the case of larger seeds cover more deeply. In soils liable to be covered with moss the earth to cover the seeds may be burned to prevent the growth of the moss. The pots can either be watered about an hour before the seed is sown or immediately after, taking care in the latter case to avoid disturbing the seeds. The pots containing the seeds must be kept shaded, and the soil never allowed to become dry. When the seedlings appear keep them near the glass and give plenty of air, but do not allow them to be scorched by the sun. Some of the seeds may not germinate for months, and all the pots should be retained for at least a year before presuming that the seeds will not grow. They may also be sown in small drills in the open ground if kept shaded, and the surface never allowed to become dry. The seeds ought to be sown very thinly, and the seedlings pricked out when large enough to handle into other pots or the open ground.

American Productions and Water Lilies (Amateur).—We did not misunderstand your letter, though the one you send now is not quite the same. Some of the newer Water Lilies are of necessity high in price because they are scarce, and they cannot be sold at what you regard as a "cheap rate" till they are much more plentiful. Some of them are not obtainable anywhere at anything like the prices you mention.

Flower Beds (J. B.).—You seem to desire "all the principal carpet bed and flower bed designs" in two books, which will also teach you "how to draw the design." You will find many and varied flower and carpet bed designs in the "Parks and Gardens of London," published at 12, Mitre Court Chambers, Fleet Street, London, E.C. You can obtain it for 2s. 6d. by ordering through a bookseller, or for 2s. 11d. by post from the publisher. Drawing can only be learned by careful and continuous practice, the same as the art of writing is acquired. There must be evening drawing classes in the city near which you reside, and in no other way could you learn the art so well as by attending them. Both geometrical drawing and freehand sketching are valuable acquisitions, and may be of great service to a gardener. When you can draw well all the designs in the book mentioned, you will be able to copy any others, and originate some of your own.

Rust on Clerodendron fallax Leaf (Inquirer).—Yes, we "see" the Bordeaux mixture has not affected the "fungus," because it could not be discovered by the highest power of the microscope at our command, which is sufficient to show everything there is to be seen in the shape of an organism. There certainly were plenty of "rust spots," and these greatly disfiguring the leaf; but they are caused by a member of the animal kingdom, a small mite with a venomous bite, which sort of half burrows in the leaf when hatched from the egg, of which you may see some with an ordinary double pocket magnifier, and abundant numbers with a microscope of about 50-diameter magnifying power. The eggs are globular, shining white or silvery, and from these the mites emerge in the course of a few days, and at once pass their beaks or jaws into the tissues, giving rise to little pustules on the under side of the leaf and to brown spots on the upper surface—the well-known "rust" of Gesneras, Gloxinias and Begonias. It is a species of Tarsonymus, nearly related, if not identical, with the Pelargonium leaf rust insect (T. pelargoni). Tobacco juice at a safe strength has been found useful against the minute invaders. Frequent fumigation or vapourisation deters the pests; but the direct application of the nicotine to the leaves is the better preventive and remedy, taking care not to use it so strong as to injure the plants.

Growing Violets for Profit (W. S.).—We have grown Violets in both the modes you mention by the thousand, and prefer the frames. You must remember that in an unheated house the pots must be protected from frost in severe weather. The plants need not be very large for culture in pots. They are grown from suckers or offsets every year in an open position, having the soil well enriched and firm to secure a sturdy habit and bold crowns, runners being kept down. Such plants, if kept clean, can be lifted in the autumn, potted as you propose, but getting as many crowns as possible into a pot, without overcrowding, or well clear of each other, and removing the old outside leaves, as they have then done their summer's work, in storing matter for the development of flower buds. The best varieties we have grown in pots were Princess of Prussia, a single large-flowered purple, similar to Wellsiana; Marie Louise, mauve lavender blue with reddish purple shades of colour; De Parme, pale lavender purple; Count Brazza's White, the three last being double Neapolitans. For flowering in frames, the plants must be well grown outdoors, lifted carefully, and placed in the frames in September, using good rich soil, and raised so that the plants are well up to the glass. They cannot have too much air, only using the lights to throw off heavy rains, then tilting them at the back. In frosty weather protection over the glass will be necessary, not allowing the sun to fall on the plants whilst frozen, nor to act on the frames when thawed without ventilation. The varieties named are excellent for frames. Get them true, and do not bother about others. The plants will give you flowers from September to April inclusive in all but severe frosty weather. By all means sell near home if you can, otherwise bunch and send to market, making due arrangements beforehand. They only pay under the best of management. Given this also to what you may grow in the house or frames in the summer, the combination ought to leave a fair margin of profit. Some persons succeed, others fail.

Names of Plants.—We only undertake to name *species* of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (S.)—The flower sent is a small form of the Spring Snowflake, *Leucoium vernum*. (F. S. E.).—1, *Begonia metallica*; 2, *Phormium tenax variegata*; 3, *Acacia cultriformis*; 4, *Hedychium Gardnerianum*. (B. H.).—1, *Asparagus tenuifolius*; 2, *Myrsiphyllum asparagoides*; 3, *Jasminum Sambac fl.-pl.*; 4, *Bambusa Fortunei*; 5, *Freesia refracta alba*; 6, *Davallia canariensis*. (G. M.).—1, *Dendrobium Phalaenopsis Schröderianum*; 2, *Sparmannia africana*; 3, *Dendrobium nobile*. (Ignoramus).—*Asparagus deflexus*.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (W. J.).—If both the fruits came from the same tree, they well exemplify the difficulty of naming. One is conical and ribbed, with a short thick stalk set in a shallow cavity; the other is inclined to be oblate, not ribbed, with a distinctly slender stalk set in a deep cavity. Both cannot possibly be typical, but a fruit between the two would resemble Calville Rouge d'Hiver. (S. O.).—1, Striped Beefing; 2, Alfriston; 3, Sturmer Pippin. (B., Herts).—1, Nec Plus Meuris; 2, Joséphine de Malines.

COWS AND THEIR CARE.

It seems a wonderful thing that a few gallons of milk require such an immense machine as a cow for their production; but so it is. The great unwieldy mass of flesh on four legs that requires much food and care is our only vehicle for the produce of one of our most valuable articles of food.

The milk of smaller animals, though at times used for domestic consumption, can never fill the place of cow's milk. There is first the smaller quantity, but the great fault lies in the generally curious flavour of other milks—flavours that require much time and a hearty good will to adjust themselves to the public taste. As a rule, it is the true sign of a disordered stomach or system when fresh milk proves unpalatable—the food is so natural, so easily assimilated, that it is found in every menu in some form or other. Happy those who have the chance of a full supply daily! We mean plenty to drink (if liked), plenty for puddings, and plenty to dilute the tea and coffee cups. It is a great wonder to us that milk and its side adjuncts are not dearer.

Except those well acquainted with animal life, few can conceive the immense quantities of food required to produce the framing milk. As we said before, the cow has a great bulk, and that bulk is not sustained on air. Watch a cow out at grass, except during the heat of the day, and certainly during the night, she is honestly and steadily at work—munch, munch. Of course people will say the rent of grass land is not heavy, but she passes a great deal of her time in close quarters, when all food and water has to be separately served; what about rations then? Indeed, even during the summer months the wise farmer supplements the grass by giving some more concentrated food while she is tied up for milking. It is only for about three months that a high milking average is maintained, then the quantity steadily diminishes till it is essential that she should have a resting time before the next calf appears.

There has been much discussion lately as to sanitary cow houses; this quite as much in the interest of the cow as the milk consumer. Where poor, wretched cows are tied up year in year out there is the greatest need of supervision; but at present we seem to be running a good chance of being too sanitary. We are just off to the other extremity, and stand a great chance of killing cows by too much fresh air as we have hitherto done by allowing the evils of overcrowding. To keep up a good supply of milk warmth is as essential as food, and huge draughty cow houses will probably induce some dire lung disorders, as well as materially lessen the milk supply.

We do not want to be mistaken. By all means have plenty of light and air, but no draughts. Some local authorities are insisting on 800 cubic feet for each cow. Now we should hardly think this necessary; indeed, so great an authority as Primrose McConnell considers that 600, or even 400, cubic feet is a very good allowance per cow. It would be a serious addition to a cowkeeper's expenses if he had to put down some form of heating apparatus to rectify the too great flow of fresh air in his cow houses.

Much has been written and said *re* the cleanliness of cows. When at large there is little to complain of; it is those tied-up which get themselves into such messes, and we find few cow standings properly adjusted. The British workman is a bit pig-headed. He cannot see, or will not see, why a standing should be made to slope towards the gutter. The slope need not be very great, indeed it is better not so. An inch is quite enough, but the gutter behind must be at least 7 or 8 inches deep. Some breeds of cows, too, appear of a cleaner nature than others. The great, heavy, blundering Shorthorn appears to get herself in the way of dirt more easily than the smarter, trimmer matron. There is a great deal of cleanliness necessary in relation to the milking vessels, and the state of the milkers. It has been proved over and over again that a cow pays for grooming.

We have heard much about the aggravating attacks of the warble fly. Well, this pest, as we have said in previous articles, is quite under our control. The means are so simple, the remedies at hand, that it is only sheer idleness that allows our cattle to be thus tormented. Many remedies are suggested, but the simplest are the best, and a decoction of a well-known sheep dip applied at frequent intervals will not only stop the ravages of the warble fly, but will kill any other vermin that may be found on the skin.

A herdsman interested in his charge will always find time for a little extra grooming without the master being constantly on the look out, but a word of praise has a wonderfully stimulating effect. We all like to see our efforts appreciated, and a good understanding between master and man tends much to the well-being of the stock.

WORK ON THE HOME FARM.

We see in the papers reports of slight frosts in some parts, but with us it has been extremely mild, so that every time we pass the Turnips we see a difference in the height of the tops. Some are 2 feet high now, and unless checked they will ere long show signs of flowering. The Swedes, too, are beginning to run to seed, and will lose much of their quality. Daily papers report a touch of winter in Southern Russia, so perhaps we may have a check yet.

Some Wheats would nearly cover a hare, and fears are expressed that they are too forward. We hear of farmers being advised to eat their Wheat off with sheep folded closely on the land. This may do very well on good land very high in condition, but the circumstances of the case would have to be very special indeed to induce us to put such an idea into practice.

We should prefer to give the Wheat a thorough harrowing; a good knocking about will keep it back, and if half of it be pulled up no harm will be done, for it will soon fill up again. We knew of a case where so much young Wheat was pulled up with harrowing that it had to be heaped and carted off, but the crop was the best the farmer ever grew.

Referring again to the Turnips, we are shown how necessary it is to store in autumn the roots required for consumption after January. Weather makes little difference, and the expense is always returned with good interest. If the mild weather should continue and Swedes go on running, the tops had better be cut off with a Turnip hook a couple of inches above the bulb. This will check them until they form a fresh top.

Lambing is now becoming general, and we would remind our readers that the sanitary condition of the lambing fold and pens is the chief essential to a fortunate and successful lambing period. If a new pitch for the fold cannot be had every year, then the old site must be well cleansed and disinfected before use. When lambing is half over, the bedding should all be cleared away and new brought, the ground and fencing being well watered with disinfectant. All dead lambs and decaying matter should be buried at once, and not left on the pen roof, as we have so often seen.

The ewes must not be kept in the pens any longer than absolutely necessary. As soon as the lambs can and will follow them they are better in the open air.

NATIONAL POULTRY TEST.

MANY of your readers may be interested to know that some 150 landowners, tenant farmers, and others have signified their intention to take part in the above test scheme; and as these are widely distributed over Great Britain, we may reasonably hope, twelve months hence, to be able to determine as to whether egg producing can, or cannot, be made a profitable branch of our agricultural industry.—K. B. BAGHOT-DE-LA-BERE.

[We publish the above information. The "test" referred appears on page 630, in our issue of 30th December, 1897. On page 47, 13th January, 1898, the scheme was commented on by a writer who has tested the question of egg production on his own farm. Many trials of a similar nature to that proposed by Mr. Baghot-de-la-Bere have been made from time to time during the past forty years. Though a few of these were promising at the first, they did not by any means subsequently equal the anticipations of their promoters, and it may be suspected that the figures which may be produced from the results of one or two years' experience will be inadequate for fully and fairly representing the profit and loss of egg production in one acre wired-in grass runs.]

13th.—Almost continuous rain from 6 A.M. to noon; sunny afternoon, and fine night.

14th.—Fine and bright early, but not much bright sun after 11 A.M.

15th.—Overcast morning; a little sun in afternoon; fine night.

16th.—Bright sunshine almost throughout.

17th.—Overcast, with occasional spots of rain early and in evening; fair day, with intervals of sunshine.

18th.—Dull, damp, and rainy from midnight to 2 P.M., and very wet snow till 3.30 P.M., then clearing, and bright night.

19th.—Almost cloudless early; bright sun all morning; cloudy at times in afternoon.

The fine weather with high barometer continued till towards the end of the week, but temperature and pressure fell towards the close, and the weather became unsettled.—G. J. SYMONS.

BARR'S 21/- COLLECTION OF VEGETABLE SEEDS

Will give a constant supply of Vegetables all the year round. The Seeds are all of the most approved varieties, and, as will be seen, the utmost liberality has been evinced.

1898-FORBES' CATALOGUE-1898

(Over 150 Pages, nearly 150 Illustrations)

Of FLORISTS' FLOWERS and HARDY BORDER PLANTS, is got up regardless of trouble or expense, with the result that it is by unanimous consent pronounced the most comprehensive, most accurate, most reliable, most complete, and best extant.

It gives full and accurate descriptions of everything in the way of Florists' Flowers, also colour, height, time of flowering, and price of all the best Hardy Border Plants together with their English or common names, and a mass of other valuable information that cannot be had elsewhere.

It is, in fact, a veritable reference book, invaluable to all growers of these plants, and should be in the hands of all intending purchasers. FREE ON APPLICATION.

JOHN FORBES, Nurseryman, Hawick, Scotland
ESTABLISHED 1870.

BATH'S NEW SPRING CATALOGUE, containing description, with full cultural directions, of the choicest CARNATIONS, DAHLIAS, PANSIES, VIOLAS, and many other plants, will be sent post free on application.
R. H. BATH, Ltd., The Floral Farms, WISBECH.

CARNATIONS AND PICOTEEES.—12 choice named for exhibition, 5/-; 12 choice named for border, 5/-; 12 choice named yellow grounds, 6/-; unnamed Carnations for massing, 3/6 per dozen; 20/- per 100. All free for cash. Catalogues post free.—T. LORD, Holbottom, Todmorden.

DUTCH BULBS.—J. J. THOOLEN, Bulb and Plant Grower, OVERVEEN, near HAARLEM, HOLLAND, has the honour to inform that his Illustrated Price List in English, Spring, 1898, is ready, and will be sent free on application. No charges for packing. Orders of 10/- and above entirely free to destinations in England, Scotland, and Ireland, &c. Lowest prices; first quality guaranteed.

100,000 BEGONIA TUBERS.—Large, erect flowering. Single, 12 for 2/3; 100, 16/- Double, 12 for 2/6; 100, 17/- SEND FOR LIST, FREE.—JOHN WELLS, Begonia Nursery, Ryarsh, Malling, Kent.

ALPINES, ROCK PLANTS & SHRUBS, and HERBACEOUS PERENNIALS, 2000 to 3000 species and varieties. — Catalogue, 130 pages, descriptive and illustrated, free on application, by postcard, to MANAGER, Guildford Hardy Plant Nursery, Guildford. Prices largely reduced for dozens and hundreds.

IMPORTANT TO MUSHROOM GROWERS.—CUTHBERT'S SPECIALITE MUSHROOM SPAWN. Always alike; most productive. Hundreds of Testimonials. Per Bushel, 5/-.—R. & G. CUTHBERT, Seed, Bulb, and Plant Merchants, Southgate, N. Established 1797.

HEATING APPARATUS.—Medals 1875 and 1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2/6; post free, 2/10.—JONES and ATTWOOD, Stourbridge.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—HIRST, BROOKE & HIRST, Ltd., Leeds.

J. C. STEVENS' HORTICULTURAL, SCIENTIFIC, and NATURAL HISTORY SALE ROOMS, 38, King Street, Covent Garden, London. Established 1769. Sales by Auction nearly every day. Catalogues on application or post free.

GREENHOUSE SALE.—Half Price, Off Season. 7 by 5, 28/6, 38/6; 10 by 6, 42/-, 50/-; 14 by 6, 52/6, 65/-; 10 by 8, 52/6, 58/6; 14 by 10, 75/-, 88/6; 20 by 10, 87/6, £5 15/-. FRAMES, 8/9, 14/6, 22/6. FOWL HOUSES, 8/9, 10/9, 14/6. Approval.—HYPOLITE, DEPTFORD.

ALL WHO WISH GRAND RESULTS should use THOMSON'S IMPROVED VINE, PLANT and VEGETABLE MANURE. This Valuable Manure is yearly growing in public favour. Can be had of all Nursery and Seedsman, or direct from the makers, WM. THOMSON and SONS, Ltd., Tweed Vineyard, Clovenfords, Galashiels, N.B. Price Lists and Testimonials on Application. 1 cwt. and upwards Carriage Paid to all stations in Britain and Ireland. London Agent—Mr. J. GEORGE, 14, Redgrave Road, Putney. Agent for Channel Islands—Mr. J. H. PARSONS, Market Place, Guernsey. Also THOMSON'S SPECIAL CHRYSANTHEMUM MANURE. ½ cwt. Carriage Paid to all stations in Britain and Ireland.

THE WINTERLY WAVE.

ONE of our poets has written two sonnets, called respectively "Natura Maligna" and "Natura Benigna." Now, as we write, the two aspects of Nature of which the poet tells are present with us. The flowers which were wooed to come into bloom by the mild season have been assailed by wintry winds and keen frost, and have been covered with snow. To-day the sun and the sea breezes have thawed some of the snow, but much of it still lies, and the flowers peep through its thick covering. With this keen frost and coverlet of snow our story of the flowers of the time must be a short one. First must come the Daffodils, at the sound of whose name there comes a flood of joyous thoughts. Not many are there yet, but those which have come give us much delight. The quaint little Narcissus minimus was quite hidden in the snow until the sun removed its covering and again gave us its golden trumpets so dainty and small. A clump of *N. pallidus præcox*, on a sunny rockery, were bent to the ground and, so far as could be seen, looked limp and lifeless. As the day went on they raised themselves, but though no longer prone, could not throw off the snow which clung to their perianths. Singular, yet beautiful, was their appearance. Their pale yellow blossoms looked brighter and deeper against the snowy carpet from which they sprang, and the patches of snow adhering to the flowers resembled some white foam placed there to heighten their beauty. The deeper yellow flowers of the Saragossa Daffodil looked brighter as they raised themselves in the border not far from their paler sisters from the Pyrenees. Others there were just ready to open, but they must dally yet until the winds blow with softer and milder breath. Such is a description of the weather and the flowers in Dumfriesshire.

Wonderful, too, is the depth of colouring shown by the common yellow Crocus when surrounded by the snow. The bulb dealers call it "golden yellow," but emerging through the white carpet it is not golden yellow but deep orange. Deeper still is a little Crocus which came here from

PROFITABLE FRUIT GROWING FOR COTTAGERS and SMALL HOLDERS of LAND. The Gold Medal Prize Essay. By J. WRIGHT. Written for the Worshipful Company of Fruiterers. Demy 8vo, price 1/-; free by post, 1/3.—JOURNAL OF HORTICULTURE Office, 12, Mitre Court Chambers, Fleet Street, E.C.

Holland, under the name of *C. Olivieri Suterianus*. This is not correct, as *C. Olivieri* and *C. Suterianus* are considered by authorities on the genus to be distinct. So far as one can judge the *Crocus* is *C. Suterianus*. It is a small but pretty flower, deep orange in colour, and less liable to injury from the storms of the early season than larger varieties. The hybrid *Chionoscillas* have begun to bloom. There are many from seeds saved from one of the true *Chionoscillas*—i.e., the progeny of a *Chionodoxa* and *Scilla bifolia*. Some have gone back to the *Glory of the Snow*, others are *Scilla bifolia*, and nothing more; while some few show their hybrid origin, and are *Chionoscillas*. A few hybrids between some of the other *Chionodoxas* and other *Scillas* ought to give us new and welcome forms.

Very beautiful are the *Lenten Roses*, and those who have plenty of space might well devote some of it to raising and testing seedlings of these *Hellebores*. The charms of a great number are only revealed to him who lifts up the blossoms to examine the interior of the flower. Rich purples, pale roses, whites, and other shades present themselves, with some beautifully spotted forms as well. Those who cannot save seeds from their own plants, or who are not possessed of *Lenten Roses* of the most advanced types, will find that good strains can be obtained which will yield flowers of the greatest beauty. As the seeds are generally slow of germinating they may with advantage be steeped in tepid water for twenty-four hours before sowing. I prefer sowing in pots and keeping these under glass, but some are fairly successful in raising seedlings in the open ground. One very good gardener of my acquaintance grows many from seeds sown in the border under an Apple tree; they are slightly covered with soil, and then with a slate, which is pressed down on them and left until the young plants have made some growth round the edge of the slate. I had intended to say something about the best of the *Lenten Roses*, which may almost be reckoned among florists' flowers, and also a few words anent the several *Helleborus* species of less striking colours but of a modest but attractive character. Space will not permit at present, and a brief *resumé* must suffice for what mention remains of other flowers.

There are patches of *Squills*, bright blue and effective, amid the snow. *Scilla bifolia* in several varieties and *S. sibirica* are there, and even when the snow has gone they contrast with the *Galanthi*, which will remain. The earlier *Snowdrops* will soon be over, but there are several species or varieties which have not reached their full beauty. *Poppy Anemones* look gay though a little tarnished by the weather. They are not numerous yet, but cast in the shade, so far as size is concerned, the exquisitely beautiful flowers of *Anemone blanda*. Bright are the bushes of *Erica carnea*, red and white; pleasing are the early *Saxifrages apiculata*, *Boydii alba* and *Burseriana*; welcome are the *Primroses* and the few *Auriculas* which keep them company. The *Snowflake* is not yet over, and the charming *Rhododendron præcox* has thrust its coloured petals through their enveloping sheaths, and only awaits a few days' sun to open. Faint-coloured and faded have grown the *Winter Aconites*, but *Iris reticulata major* will open soon, and Dr. Stuart's variety of the bright *Primula marginata* has commenced flowering. As the sun strengthens with the advancing day the clumps of *Crocus* open and display their glowing various-coloured cups before our eyes. Though winter is with us, they entice us to lay down the pen and go into the garden to see their beauties—familiar, yet ever new.—S. ARNOTT.

LAWNS AND ALLIED SUBJECTS.

(Continued from page 170.)

IN connection with our last paper, chiefly occupied with effective lawns from a landscape view, as well as the advantages derived from judiciously planned open stretches in the matter of keeping, it would be scarcely fair to our beautiful trees, the *Coniferæ* principally, to exclude them from a passing thought not irrelevant to our subject. In the pleasure grounds nought but the greensward as a groundwork can give, as a rule, the most pleasing effect; and in turning from ideal primness to the picturesque beauty of those grounds probably known as the shrubbery, and probably, too, not in the immediate line of vision from the windows, a greater freedom from that ultra-neatness, which is never to be condemned, is in fact essential to the lawn proper, gives full facility in the way of top-dressing or other means to the end of doing the trees justice.

Here their arch enemy, the lawn mower, shall not come to mangle their lower members or bark their trunks. Being still in the kept grounds, however, obviously a margin on each side of the walk, entailing one or possibly two breadths of the mower to keep all in order, is necessary, especially to prevent grasses seeding upon the gravel. In deep bays or in the background where groups or specimens of ornamental trees can be made happy, a couple of scythe mowings during the season will be all-sufficient. This system provides, too, for the naturalisation of favourite flowers, such as nodding *Daffodils*, "that come before the swallow dares," with the humbler *Snowdrops*, *Crocuses*, *Scillas*, and *Dogstooth Violets*. These will be well over and sufficiently matured for the first scythe mowing, which is no impediment to their welfare; another mowing at the end of the summer will keep all presentable so far as this position is concerned. I may be pardoned in straying a little from the text if readers will contrast such trees dotted about a lawn, probably starved, possibly damaged, with the more natural condition obtaining with "unkept" grass, and above all things justice must be done to the lawn proper, to which we now return.

MAKING NEW LAWNS AND RENOVATING OLD ONES.

From early autumn and well on into spring a fairly long season obtains for those who perforce of circumstances cannot always do what is felt to be the right thing at exactly what is known to be the right time. As a rule, we may take it that autumn for laying turf, and spring for sowing the seeds, is the soundest policy whichever of the two methods is adopted. In the matter of turfing, if the operation can be concluded before severe frost is to be expected, it is a wise course for several reasons, one of which is that if the new turf can be laid early, ere the soil has cooled down, root action is promptly induced, the grass is fairly established, and better able to withstand a spell of parching weather should such occur the following season. Delays often bring difficulties, too, in the matter of a quantity of frozen turves on hand, as I once found when caught in the act of carrying out some rather extensive alterations by a spell of Arctic severity, for after some considerable time ere we could proceed, not only discolouration of the grass, but a good deal of disintegration of the rolled up turves by the action of frost gave considerable trouble in the laying process.

The preparation of the ground, whether for turves or for seeds, is of primary importance, considering the permanent character the lawn is to hold. Unfortunately, in the case of new buildings, a considerable quantity of excavated subsoil is too often available for finishing off surface levels, and responsible for bad work in the best position—near the house; this, of course, in cases where the subsoil is sour, tenacious, and generally unfit. But recently an example came under notice where similar uncongenial soil had been formed into mounds near the dwelling, and planted at some considerable expense with choice shrubs, which lately stood as the dead or dying witnesses of a mistake. In the matter of lawn-making such mistakes are costly in more senses than one.

Too much pains cannot be taken in a thorough preparation of the soil, first by the vigorous removal of old tree stumps or other obstructions, and then by draining at an adequate depth if the subsoil renders any draining necessary; in fact, all the preparations considered necessary for a good kitchen garden, so far as the soil is concerned, may well be given where the object is to make a perfect lawn, and retain it in perfection.—SYLVA.

(To be continued.)

BROWNEAS.

ANYONE who has the room at his disposal in a large house that can be kept at a stove temperature would do well to include one or more species of this genus among its occupants. The recommendations in their favour are, that in most cases they take high rank as foliage plants, and in almost every instance they are among the finest of stove flowering shrubs.

At Kew several species may now be seen in flower in the Palm house. *B. grandiceps* is there represented by a plant 20 feet high. The handsome pinnate leaves of this particular plant are between 2 and 3 feet in length, and are made up of from eighteen to twenty pairs of leaflets, many of which are 8 inches long. The flowers are bright red, and produced in round heads 6 to 8 inches across. Near by is a dwarfier but much better furnished plant of *B. Crawfordii*. This is a hybrid between the former and *B. macrophylla*. The leaves are not so long as in the former, but the leaflets are larger. The heads of flowers are quite as bright-coloured as in *B. grandiceps*, and if anything larger. This plant is planted out, and grows far more luxuriantly, and at the same time flowers more freely, than plants in pots. Others are to be seen in flower, but at present these are the most showy.

An additional item in favour of *Browneas* as ornamental foliage plants is, that when the leaves are first developed they are beautifully mottled with brown and green, and contrast finely with the dark green of the old foliage. Although a large house is necessary to grow these plants to perfection, plants a few feet high, which have been rooted from cuttings, can be flowered successfully.—D. K.

DENDROBIUM SPECIOSUM HILLI.

THE "heroic treatment" of *Dendrobium speciosum Hilli*, recommended by your correspondent, "Herefordshire Incumbent," is quite unnecessary. I have four or five large plants of *Dendrobium speciosum* and *Dendrobium speciosum Hilli*, which flower abundantly every year, and have done so for many years, except that if one of them has an unusual quantity of flowers one year, it will sometimes not flower the next year. They are now in flower, and I counted just eighty flowers on one spike on one of them. They grow summer and winter on the front shelf of a cold greenhouse (just kept above freezing in very cold weather) and receive no attention of any kind except an occasional watering. The pots are filled chiefly with stones and broken crocks.—C. W. STRICKLAND.

ONCIDIUM SPLENDIDUM.

THE beautiful golden yellow blossoms of this Orchid, produced on long branching racemes, are almost exact counterparts of *O. tigrinum*, of which species many botanists agree in calling it a variety. But so distinct in every way is the growth and treatment required that it would lead to much confusion in gardens were this strict botanical system adhered to. The pseudo-bulbs are roundish, deep shining green, the foliage very thick and leathery, of a bronzy green hue, quite different from the bright green of *O. tigrinum*. The flower spikes appear at the side of the last formed pseudo-bulb, and on strong plants are from 2 feet to 3 feet high, much-branched and many-flowered.

The sepals and petals are yellowish, blotched with chestnut brown, but they form rather an insignificant part of the whole. The lip is of the brightest chrome yellow, perfectly clear in colour, and of distinct outline. *O. splendidum* (fig. 29) is a strong healthy grower when in suitable quarters, and can be allowed pots of medium size, well drained, and a free open compost. This may consist of equal parts of peat, rid of all earth and sand, and sphagnum moss, in about equal proportions, plenty of large rough lumps of charcoal and crocks being mixed with this to insure the ingress of air to the roots. The best plan is to fill up to within an inch of the rim with drainage, and leave the upper inch for compost, this doing away with any suspicion of closeness, yet providing a good rooting medium.

The temperature of the Cattleya house suits it well while making its growth—in fact, it is suitable all the year round; though where a house is set apart for the Mexican *Lælias*, the plants may be placed here for a month or two, if they seem inclined to rest that long. The growth, as a rule, pushes from the base about March or April, and continues growing until late in autumn; then if the spikes do not appear at once a short rest may be given, but as a rule if there is any rest it is after the flower spikes are over. All the year round a nice light position should be allowed, the sun shining full on the plants after closing time, this causing a brisk buoyant atmosphere, in which growth is very rapid.

Fire heat in dull weather is necessary to keep the temperature up to the mean, but it is better not to drive this much. Growth under these conditions is soft and tender, easily damaged by the slightest check, and apt to be attacked by spot. Light syringings in bright weather are refreshing to the plants, but must not be overdone, and should be entirely discontinued in dull weather. Water at the roots should be freely applied as long as growth is active, but when the plants are entirely at rest only enough to prevent shrivelling is required. *O. splendidum* was known and cultivated on the continent years before it was in Britain. It flowered first in this country in 1870, but was rare and valuable for many years afterwards; but Messrs. Sander having imported it in quantity, it soon after became well known.

CATTELEYA TRIANE.

The many varieties of this useful and beautiful Cattleya are just now in their fullest beauty, all tints from the purest white to the deeper tints of rose and purple being found among them. It is a widely distributed species, naturally being found over large tracts of country in South America, and doubtless this in a manner accounts for the great variation found in the plant. The habit is similar to that of most of the labiate Cattleyas, and with them it may be easily grown with proper care. Small plants may be grown in pans suspended from the roof, this allowing a good light to play all around them, and making them dry readily at the root after watering. Stronger plants may be grown in pots in the Cattleya house on a stage as near the glass as convenient.

Let the pots be clean and thoroughly drained, allowing of a couple

of inches of good rough material, consisting of peat and sphagnum moss, with a liberal addition of crocks and charcoal. The drainage crocks should be protected with a layer of the rougher portion of the moss, and the plant must be placed in position with the base of the leading pseudo-bulbs a little above the rim, the compost being brought up to them in a convex mound. The best time to repot is soon after the flowers are past, for if left long after this the young shoots at the base will be getting ahead, and are apt to be snapped off with the dibber, this causing the plants to be dependent upon back breaks, which are never so strong as the first lead.

After potting careful watering is necessary until roots are again somewhat freely emitted, when the supply must be gradually increased. The plants require as much moisture when growing and rooting freely as do most Orchids. The growth finishes in the autumn, each pseudo-bulb that is strong enough having its flower sheath. The plant must now be kept in a good light and exposed to as much sun as possible without damaging the foliage. Reduce the supply of water by degrees, but never entirely withhold it, especially toward the end of winter, when the flowers are forming inside the sheaths. Many fine plants have been ruined by inattention at this stage, and their shrivelled appearance afterwards is attributed to their not being strong enough to flower, while really they are starved for want of water.

Among varieties the best of all is the albino form, *C. Trianeæ alba*, this having flowers of the purest white without a tinge of any colour except a yellow blotch on the lip. *C. T. Schröderiana* is a delicate and beautiful form with sepals and petals of the palest blush and a golden yellow centre to the lip. *C. T. delicata* has pure white outer segments and a bright blotch in front of the lip. The variety *rubella* is a very richly coloured form, the large crimson-purple blotch on the lip being exceptionally showy. Many others may be mentioned; in fact their number is as large as those of any species, but a repetition of their features does not make very interesting reading.—H. R. R.

FIG. 29.—ONCIDIUM SPLENDIDUM.

HARMFUL AND HARMLESS GARDEN MOTHS—16.

"WHAT a beautiful moth!" said a person, who made no pretension of special admiration for insects, when he observed a specimen of the bordered Gothic resting upon a tree on a July day. Sometimes we wonder why the old naturalists chose the names they did for many species; there is nothing one sees particularly Gothic about *Neuria Saponariæ*, nor its two kindred species, unless, indeed, it was fancied that the transverse lines on the wings resembled, in their tracery, the form of Gothic columns. The beauty of the moth arises from the contrast between the rich brown wings and the dark and lighter markings upon them; the dark take the form of black spots or lunules, the others are pale lines or rays. The fringe of the wings is of two colours, and the eyes are very hairy. It occurs, not abundantly, in the South of England.

From its feeding on low plants near the earth, or now and then beneath its surface, the caterpillar is seldom noticed; it has a horny plate behind the head, and is smooth, in colour reddish brown with faint stripes. It has been taken on several species of *Silene* and *Lychnis*. Guenee says it is fond of the White Campion. Smaller in size is a Gothic moth found in Devonshire and the Isle of Wight, called *Heliophobus hispidus*; rather rare, it has no black tints, but many light spots and lines upon the ground colour. The caterpillar feeds upon the roots of various grasses. Allied to this is a moth too well known in some localities, but it is seldom seen about gardens; it is somewhat like the Gothics, but is an August species, the caterpillar feeding in early summer. This is the antler (*Charæa graminis*), which sometimes swarms upon commons and meadows, causing much damage to the crops of hay in Sweden. With us, it is

chiefly noticed in the north. Of all the grasses it seems to prefer *Poa annua*.

Moths cannot manage to hide themselves in the grass of a well-clipped lawn, but I have often seen children amusing themselves in hunting for these insects on lawns or banks where the grass has been suffered to grow long. A variety of species hide from view thus, in the daylight, those more particularly which are grass-eaters while in the caterpillar stage. Two of these that are tolerably common throughout Britain are the light arches and the dark arches, moths which occur about midsummer, or a little later. The first, also called *Xylophasia lithoxylea*, is a whitish brown, with dark streaks and blotches; the thorax has a crest, and the tail a large tuft. The stout caterpillar, which is dull white, marked by rows of black shining spots, has been dug up in May at the roots of grasses, and about the same date that of the dark arches, or *X. polyodon*, becomes adult. In appearance it is similar to its relative; but the moth is very differently marked, being of several shades of brown, conspicuously blotched and lined; part of one of these lines exactly resembles the letter W. Some of the northern specimens of the species have the upper wings all dingy black. Then upon the roots of Poas and other grasses lives the caterpillar of a pretty moth, which we see passing from flower to flower in broad daylight, not concealing itself, as do most of the Noctuas. It is found throughout England and Ireland, and is called the ear moth (*Hydroecia nictitans*), for, in the centre of the fore wings, which are of a deep reddish brown, is a white spot resembling the human ear, also sundry lines across give the appearance of network. It is seldom that any of these caterpillars do noticeable harm to lawns.

We come now to a genus too well known to the gardener, especially while the insects are in the caterpillar stage, when many of them show no inclination to hide themselves, but feed boldly upon the produce of our gardens. The caterpillar of one familiar species I have had brought me several times as a curiosity; seemingly something about it caused wonderment, though it is not so notably different from many of its brethren, but is conspicuous by its marks or stripes on the sides. It is not, however, the caterpillar, but the moth itself, that gives the name of "the dot" to the species, suggested by a pure white patch on the wings, with a smoky centre. The Latin name is *Mamestra Persicariae*, not very appropriate, since it is by no means attached to *Persicaria* as food; indeed it is a caterpillar of general tastes, eating various herbaceous plants and shrubs, ranging from *Pelargoniums* to *Roses*. Quite late in autumn I have seen it on flower beds, but it is chiefly noticeable through August and September.

One singular fact about this caterpillar is that we find it of two colours, green and brown; the former usually produce male moths, the latter females. One of these, when we have once recognised it, we are sure to know again by his small mottled head, behind which is a dark green square patch on the back, and the hump upon the last segment, also by the characteristic double row of V markings pointing towards the tail. The winter is passed underground, as a chrysalis, at no great depth. Then there occurs about gardens in some counties, while in others it is unknown, the moth called the white colon, *M. albicolon*, taking these names from two white dots near the lower extremity of the greyish-brown fore wings, which are like the colon sign. This is an earlier moth, coming forth about May, when it flies in waste places; it usually lays eggs on some *Chenopodium*, but having a partiality for Lettuce. It also enters gardens, where the caterpillar has been taken upon this vegetable, and sometimes on others. It is very smooth, of a grassy green with a few pale stripes, and easily escapes notice; when alarmed it drops instantly, curled into a ring. The season for it is June and July. A curious contrast to its companion species is the crescent-striped moth, which is found plentifully along the banks of the Thames below Gravesend, the caterpillar living on Sea Wormwood.

Now we come to the moth most detested of all the Noctuas, for which neither gardener nor farmer will say a good word. It is as frequent nearly in the flower as in the kitchen garden. The only thing I can say in its behalf is that, to my knowledge, the caterpillar does not meddle with fruit trees. The Cabbage moth, or *Mamestra Brassicae*, was, no doubt, created for some good purpose. One naturalist of note suggests it may have helped to keep down a superabundant growth in wild districts; but we would gladly exclude the species from our gardens now. The moth does not vary much. The expanded wings measure about 1½ inch; these are brown, indistinctly mottled with darker brown and grey. Evidently there is a succession of emergences through the summer, as we observe moths from May to August, and it is not likely that the life of an individual moth lasts more than a week or two. This fact makes it more difficult to dispose of the moths than if the appearance of the brood was nearly simultaneous, as it is in some species. No moth so enrages the entomologist. When he has spread his sugary compound upon the tree trunks he hopes for rarities, and often beholds instead an eager swarm of Cabbage moths. But gardeners will bless him for destroying some of them.

Certainly the caterpillar is particularly fond of all the Cabbage tribe, and it is not surprising that we come across people who, on its account, refuse to touch Cauliflowers, or any close sort of Cabbage; for, as Mr. Wood remarks, the cook may wash her vegetables thoroughly to appearance, but deep in the heart, much grieved by the salt, yet unable to make an escape, are sundry of the fattest caterpillars, which are fondly cooked with the Cabbage, and eaten. After boiling, indeed, the creature becomes paler, and not very distinguishable. When alive it is brown, yellowish brown, or green, varying somewhat; occasionally there are markings of black and white. It feeds on almost every plant, useful or ornamental, and is busy both night and day; when adult, it descends to the earth for the winter. Just now there is an opportunity of killing many of the pupæ during the digging customary at this season, when it is possible to let poultry run over the ground; they will pick them up by hundreds. Also, they are eaten by mice, and possibly by some carnivorous beetles.—ENTOMOLOGIST.

ARTIFICIAL MANURES.

"A. D.," on page 147, February 17th, after referring to artificial manures being "like patent medicines," says, "Everybody has his own favourites, in which he believes." I quite understand this, as from experience I have found that different soils require different manures; but for anyone to say "it is difficult to show that the world is one whit the better for them" is (in my opinion) a random expression.

I presume your correspondent is, or has been, in a position with a good supply of natural manures at his command, such as poultry manure from the home farm, which is excellent for Vine borders, and cow and sheep refuse from the park, which, when put in a tank of water and a little soot added, makes a good liquid manure; also the manure from stables where the horses are fed on the best food stuffs. A gardener in a private place with the above manures at his command need not trouble himself much about artificial manures.

But what about the market growers, with their acres of glass, who have to buy nearly all their stable manure from contractors in the nearest town, and then probably have to cart it two or three miles? The cost of cartage is enormous compared with the manurial ingredients it contains, for the most soluble portions may have been washed out by adding water to make it weigh heavier. Therefore the market growers do not use more than is essential to supply their soil with sufficient organic matter.

They find it more economical to purchase artificial manures. I use a large quantity, and such experiments as I have conducted and observed have led me to realise the practical usefulness, not "worthlessness" of artificials. Without them market growers could not produce the fine crops necessary to make their business pay now competition is so keen. Common sense is all that is required when applying artificial manures. Mistakes are often made by thinking that as a little does good much will be better, consequently too much is often given, which does harm, and then the grower condemns the manure. There are, I believe, growers now who purchase the separate ingredients, and mix their own compounds, but scientific knowledge is required to do so with advantage.

I hope "A. D." is not so disgusted with artificial manures as to prevent further experiments, but in trying he must be exact in his methods, and take proper notes of the results. In the meantime I hope the up-to-date readers of this valuable paper will keep artificial manures on the brain until they find out the best kinds for stimulating their crops, and helping to exterminate the eelworm. I must congratulate "A. D." and his "gardening friends" on having no experience with this terrible pest; but there are plenty of equally "good cultivators" who have a great deal too much of such unfortunate experience.—A GROWER FOR MARKET.

ON the above subject your correspondent "A. D." (page 147) seems to have "climbed down" considerably. He thinks that if unable to "elevate and instruct," he will "delight and amuse." He began by accusing Mr. Dyke of extravagance in the application of artificial manures, he ends with a feeble joke—"As to killing the eelworm, the latest specific seems to be found in tickling its tail with superphosphate, to make it laugh, then choking it with a big dose of basic slag."

"A. D." evidently lives at an elevation to which no ordinary "grower" can hope to climb—a paradise where the eelworm has never been allowed to enter. "I have had no experience of eelworm, and amongst my gardening friends, who are good cultivators, the same ignorance prevails." What think you of this, Messrs. Abbey and Iggulden? Can we prevail on "A. D." to publish the secret he holds, so that Mr. Dyke and his numerous eelwormy friends may know how to arrive at that blissful state where the eelworm has ceased from troubling, and artificial manure vendors and their "cant" are at rest?

In the neighbourhood where I reside the eelworm has caused an enormous amount of damage, but probably the owners of these establishments cannot be reckoned among "A. D.'s" "gardening friends, who are good cultivators." Now, "A. D.," rather than carp at one who has found a remedy from these evils, let us appreciate all attempts to make the path of the cultivator easier and pleasanter.

The fact that many mixed artificial manures are worthless should be known by this time to all readers of the Journal, but they should also know that without artificials in these days of intensive culture failure will be their lot.—A. B. C.

NATIONAL CHRYSANTHEMUM SOCIETY—ANNUAL MEETING.

THE members of this Society mustered in strong force on Monday evening last at Anderton's Hotel, when Mr. T. W. Sanders occupied the chair. After the Secretary had read the notice convening the meeting, he then presented the annual report and financial statement, and also submitted a statement as to the reserve account.

The CHAIRMAN, in moving their adoption, said that the annual report and financial statement as read out to them by the Secretary represented the work of the past year, and it was for that meeting to say whether the members present considered it to be satisfactory. The motion was seconded by Mr. H. J. Jones.

Mr. J. R. STARLING desired to say a few words before retiring from his post as Treasurer. He had been with them for twenty years. At first they were small in numbers, but the Society had now become so gigantic that it required someone able to give more attention to the duties. He considered he had only been Treasurer in name. What Mr. Holmes had begun Mr. Dean had followed. He reproached neither, but it was not, he thought, the way things should be done. He thought they ought to have paid auditors, and a Treasurer who could do the work. He had always done his duty and given the time he could, but the state of the accounts was not such as he liked to leave or see the Society in. The Society, he thought, was big enough now to have properly appointed auditors and to have the accounts set forth in proper form. He had no complaint to make, and he regretted leaving after being with them twenty years, but could not undertake the duties which must necessarily increase.

Mr. R. DEAN gave an explanation of several items now outstanding, and thought the Committee was justified in saying that the financial position was sound.

Mr. GEO. GORDON felt the finances required careful consideration, and pointed to the rate at which some of the items had grown, making comparisons between 1891 and the past year. He thought the great point was to pay their way before they incurred expense, and it was most important to consider what they were going to do for 1898. The amount to be provided for prizes by the Society at its four shows was £610, while it could not be expected that the income would be very largely increased. As the balance appeared to be so small, he would like to know where the money was coming from. It was a matter that ought to be faced by the members, and as an amendment he moved "That the report and financial statement be referred back to the General Committee, with instructions to prepare a proper balance-sheet, and to prepare an estimate of expenditure for 1898, and to report on the advisability of a reduction in the number of the shows, or in the amount of prize money during the current year."

Mr. J. W. MOORMAN, in seconding this amendment, objected to the statement that the Society was financially sound, and in support of which he said that the gentleman who had been nominated to fill the vacant post of Treasurer would only accept office on condition of the debts being previously paid. Mr. T. BEVAN also supported the amendment, and suggested the necessity for a proper balance-sheet, and thought the meeting should be adjourned till that was done. Another member complained that the financial statement had not been printed for the use of members.

Mr. DEAN, in replying to some of the criticisms, referred to the new schedule for 1898. Though the Society increased in numbers, yet the annual loss of non-paying members was large, and he attributed the increase of prize money to the action of the Schedule Sub-Committee, which, if not checked, would land them in bankruptcy. Mr. W. H. LEES protested as a member of that Committee.

Mr. CHOLMELEY moved that the accounts be printed and placed in the hands of the members at least seven days before the date of the proposed adjourned meeting. That, he ventured to say, was the usual commercial way, and it was not usual to ask for them to be passed without. They might be right, and no doubt were, but he considered he should see for himself. He did not believe the Society was in a position of bankruptcy.

At this juncture inquiries were made as to voting by proxy, but the Chairman pointed out this would involve an alteration of rules.

Mr. SPICER moved that the meeting be adjourned for a month, but finally agreed to three weeks. The auditors would, no doubt, prepare a balance-sheet when they knew the Society wished every liability placed before it. The Committee would also look into the question of what could be done during the ensuing year.

Mr. GORDON'S amendment having become the substantive motion, it was carried, and the meeting was adjourned to Monday, the 21st March, at 6 P.M. There was a long agenda paper, but all other business usually transacted at the general meeting must stand over until the date mentioned.

The interest in the proceedings was keen, but the discussion orderly and dignified.

REPORT OF THE COMMITTEE, 1897.

At the termination of another year's operations, your Committee can congratulate the members upon the steady and satisfactory progress still being made by the Society. Its work during the past twelve months was carried on with energy and success; its resources are as great as ever;

its supporters more numerous; it is financially sound; and its prestige knows no diminution. During the year four exhibitions were held, and, as is usual, they were of a high order of merit. The meetings of the Floral Committee maintain their interest and usefulness, and the societies in affiliation show a substantial increase.

In common with some kindred societies, your Committee took steps to commemorate the Diamond Jubilee of her Majesty the Queen by instituting some special classes, which were competed for at the November show, and proved interesting features. A Commemoration Fund was opened, and a fair proportion of the amount offered as special prizes obtained.

The Jubilee edition of the Catalogue, 1896, is still in constant demand; it has been found most useful by affiliated societies, and it will be gratifying to the compilers to know how greatly it is appreciated. Inquiries are being made as to the probable issue of a supplement; a desire is also occasionally expressed that the publication of a Year Book be continued if possible.

The Classification Committee have held a sitting, and dealt with certain varieties of incurved flowers, defining their proper position. This Committee has sought and obtained from the General Committee larger powers, which will enable them to make from time to time such recommendations affecting the exhibition of plants and blooms which it may appear desirable to adopt in practice.

A sub-committee has been entrusted with the revision of the rules; and after full and patient consideration have recommended material alterations, which they believe will, if adopted, improve the procedure of the Society in several particulars, and bring the rules generally into closer agreement with its practice.

During the year ending December 31st, thirteen Fellows and 114 ordinary members have been elected to the Society, and the number of societies in affiliation have increased by eleven.

An agreement has been entered into by your Committee with the Royal Aquarium Society to hold four exhibitions in the present year—viz., in September, October, November, and December; and the Directors commemorate the fact that the National Chrysanthemum Society has held their exhibitions at the Aquarium for the past twenty-one years, by offering special commemorative prizes at the November exhibition.

The schedule of prizes for the four exhibitions has undergone revision, and a substantial increase in money value has been made in several leading classes. A special class for twelve vases of specimen blooms of Japanese Chrysanthemums has been introduced at the November show, the President, Sir Edwin Saunders, generously giving the first prize of £20.

Your Committee most heartily thank the President, as well as all donors of special prizes at the various exhibitions, as they are frequently the means of bringing out some novel features, adding to the attractiveness of the various shows; and highly appreciate the warm interest Sir Edwin Saunders takes in the work and success of the Society.

Your Treasurer, Mr. J. R. Starling, who has been connected with the Society by membership since 1878, who was appointed Treasurer in 1879, and has held that office ever since, is compelled by ill health to insist upon the resignation of that office he, for the same reason, placed in the hands of the members a year ago. Your Committee also regret the death of Lord De L'Isle and Dudley, one of the patrons of the Society.

FINANCIAL STATEMENT.

We have received a statement of receipts and expenditure, but owing to its hurried preparation and the indistinct pencilling-in of figures we are unable to insure an accurate representation. As we should not like to incur the risk of possible errors appearing, the statement is withheld. This notification is not in the least to be regarded as a complaint against anyone, as we assume all was done that could be done under the circumstances.

DAMPING IN CHRYSANTHEMUM BLOOMS.

ANYTHING pertaining to Chrysanthemums is always absorbed by enthusiastic chrysanthemists (Why not adopt the name? It is expressive, convenient, and far more elegant than the ugly contraction "mummers") with avidity, and perhaps the following note, though unseasonable, may evoke other opinions and throw light on a subject that to me has always been a mysterious calamity—I refer to "damping."

For some years I have observed that one end of my house was always much less subject to the evil than the other, and from this experience I had placed all my most susceptible varieties at that end. I could never reason out why this end should be always so favoured beyond the other, as all other conditions of light and heat were practically the same. I may say that the plants are flowered in a house in which Camellias are planted in open beds, and the house an iron built one, consequently the evaporation from the open beds and the condensed moisture on the metal surfaces make it as undesirable a place for big blooms as could well be imagined.

There is a large cistern underground at each end of soft water, the hole being covered with a moveable flag. I have always grouped the plants over this, at the end to which I refer. At the other end the cistern has always been open and used for watering the Chrysanthemums from, as more convenient and suppositiously better for the plants, while the end which has proved so signally free from damp blooms has been watered from the tap with water which is most decidedly hard. From this I have come to the conclusion that soft water is indirectly conducive to damping. When we consider how seldom a soft water cistern is cleansed, and the nature of the water collected from the house tops in autumn, with its many abominations of decayed vegetable matter, I think it is not improbable that a condition of affairs may arise that is distinctly advantageous to the propagation of this scourge to chrysanthemists.—R. E. RICHARDSON, Wollaton.

CHRYSANTHEMUM LEAF RUST.

I HAD been expecting to see in the Journal correspondence on this subject for some weeks past, and I am therefore very pleased to observe Mr. Abbey's further report in this week's issue. I have purposely waited ere relating my experience since October last, when Mr. Abbey kindly examined the leaves I sent to England, and gave us his opinion on the question. I entirely agree with your correspondent, J. G. Mills (page 151), that it is a matter which deserves serious study and consideration, particularly as it may be considered only in its infancy.

Mr. Abbey tells us there is no evidence of the disease being distributed on cuttings or young plants before the spring of 1897. The American variety Niveus was, I believe, raised in 1893, and cultivated in England in 1894. If the disease were not evidenced till 1897 I suppose we could not saddle the Americans with the origin of the rust, unless it were dormant for two or three years, which I gather from Mr. Abbey's report might be possible.

The apparent "caprice" of the rust is, however, the question that mystifies me at the present time, as the disease reappeared here at the beginning of last month on cuttings received from England in December. It showed itself on about a dozen of these semi-rooted cuttings, and towards the middle of January I observed a few specks of the rust on five or six of my own half-rooted cuttings in a collection of some six or seven hundred. When it is considered that every one of my plants (excepting those grown under glass the whole season) were affected very badly last autumn with the disease, it seems a peculiar coincidence that the reappearance should first show itself on the recently arrived English cuttings.

I have to thank Mr. Abbey for his suggestions and warnings in October last, as I attribute to him the check of the rust for the last three weeks or so—i.e., so far as the naked eye can tell. I treated every affected part with a solution of equal parts of sulphur and lime boiled and applied with a small paint brush. A simple immersion will be found as ineffective as pouring the liquid on a duck's back. I have also since watered and syringed the cuttings and plants with a diluted solution of this mixture, and after a daily close scrutiny no visible trace of rust has appeared. This is, I think, very hopeful, but I recognise the fact that it is too early to draw conclusions. N.B.—If after boiling the sulphur and lime are allowed to deposit, and the clear liquid drawn off, no disfiguration of the foliage takes place when syringing. The Bordeaux mixture I also experimented with, and although apparently effective, I prefer the sulphur and lime for young plants.

With the view of assisting to solve the question of the origin or cause of this disease I should like to point out—

- 1, That all my plants, some six or seven hundred in pots and in the open ground, were affected in the autumn of 1897 with the rust, all excepting some three or four dozen, grown entirely under glass the whole season.

- 2, My plants came from England, America, France and Italy—old and new varieties.

- 3, The disease first appeared in my plants after much rain, and at the same time Raspberry rust showed itself.

- 4, That all the plants were apparently affected at the same time.

I have ventured to trouble you with my experiences on this subject thus early in the year in the hope that they may prove of use to some of your readers, and that the disease may be effectually checked in its career. —HENRY BRISCOE-IRONSIDE, *Pallanza, Lago Maggiore, Italy.*

HIGHGATE AND DISTRICT CHRYSANTHEMUM SOCIETY.

COMMITTEE meetings of the above Society were held on the 11th and 17th ult., when the schedule for the Exhibition to be held at the Holloway Hall on November 8th, 9th, and 10th next was settled, several classes being added to last year's schedule, making up the total to ninety classes. It was unanimously decided by the Committee that the Society should discontinue its affiliation with the N.C.S., and award its own certificates and medals. It was also agreed that certificates should be awarded to new varieties of Chrysanthemums if of sufficient merit. The Judges were also elected.

BELFAST CHRYSANTHEMUM SHOW REFLECTIONS.

I HAVE read with much interest Mr. Beckett's remarks in defence of the above in your Journal of the 17th ult., and again trespass on your space to offer a few further suggestions, as I am responsible for the reflections.

FIRSTLY.—I fully sympathise with Mr. Beckett in disclaiming infallibility as a judge, and quite agree with the editorial remark, "that two judges might have been advantageously employed at this show."

SECONDLY.—Mr. Beckett states, "Far better give an exhibitor the benefit of the doubt than disqualify." Such is usually extended to a criminal in a court of justice, but in this case we find thirteen exhibitors equally expecting that justice would be done. From Mr. Beckett's experience of Yellow Madame Carnot, he probably has another sport. My experience is that it is a distinct canary yellow, and from what I saw of it there, as well as in Edinburgh and other places, and also having seen G. J. Warren exhibited, I consider them too much alike to be termed distinct. The bloom referred to at Belfast had just sufficient primrose colouring to distinguish it from the original Madame Carnot. Making due allowance for fluctuation of colour through "timing of bud," age of bloom, and other cultural points, it will require an authority of greater fame than Mr. W. Wells to transform Mr. Jones' Yellow Madame Carnot into so pale a primrose as that exhibited by Mr. W. Mease at Belfast.

THIRDLY.—I refer Mr. Beckett to Mr. Molyneux's review of new varieties in the Journal of December 9th last, page 558. In this he gives pride of place to Mrs. W. Mease, and describes it as a soft primrose

sport from Madame Carnot. So good was this bloom as shown at the National Chrysanthemum Society's Show last November that it received the premier award as the best Japanese bloom at the show.

FOURTHLY.—Most readers will agree with me that although late I stated a clear case of card-boarding as perpetrated at Belfast. My reason for not lodging a protest at the proper time was: It was only on the second day of the show (then too late to protest) that I had an opportunity of examining the winning stands in the class referred to, and I took my notes during the quiet hours of the morning. I went through each stand in the order of the awards, and when I came to the third prize stand I at once noticed a thin disproportioned bloom of Mutual Friend, and on examination found that it was supported with a circular card-board 5 inches in diameter. On further examination I found no less than thirty-one blooms treated in a similar manner. Mr. Beckett states "that card-board or no card-board, it would have received the same award from any responsible judge." Are we to infer from this statement that he treats "card-boarding" as legitimate?

I will now challenge Mr. Beckett or any other Chrysanthemum expert to publicly state in these columns that card-boarding Chrysanthemum blooms at shows is legitimate, having regard to the regulations of the National Chrysanthemum Society.—PETER BROCK, *The Gardens, Glenmor, Drogheda.*

P.S.—I have read in your issue of 24th ult., page 172, Mr. Mease's explanation of his primrose sport from Madame Carnot being labelled at Belfast as "Yellow Madame Carnot," announced by some to have originated with him a year ago as a root sport, and this year remained perfectly true. I did not intend to further trespass on your space, but as my last letter on the subject is not yet published, I beg to ask the insertion of the following.

Doubtless Mr. Wells thought he was doing right when he directed Mr. Mease's assistant that the bloom should be labelled correctly as exhibited at Belfast, "Primrose sport from Madame Carnot." But he probably did not know the terms of the schedule until the protest was lodged against the stand on account of this bloom, the variety not being in commerce. The practice of re-labelling blooms at shows by such eminent experts is, to say the least of it, far from becoming, as we now have in commerce Mrs. W. Mease. It was apparently only after the shows were over that they could distinguish it from Yellow Madame Carnot as introduced by Mr. H. J. Jones. Having regard to these facts, all fair-minded men will agree with me that, much as I regret any remarks I have made, under the circumstances they have been quite justifiable.

COLLARETS FOR CHRYSANTHEMUMS.

Referring to "Sadoc's" remarks *re* collarets for displaying Chrysanthemum blooms, he may be interested to learn that the Ulster Horticultural Society adopted as its rules the rules and regulations of the National Chrysanthemum Society. Having regard to this fact, how are collarets permissible? Apparently special rules will have to be drawn up against their use, or let every exhibitor meet on level terms and use his discretion as to how much support he will employ further than the cup at present prescribed by the National Chrysanthemum Society. This is a matter which Chrysanthemum show committees should take timely notice of, and adopt such rules as they think best suited to promote the interests of fair and honourable competition, and thus prevent a recrudescence of what appeared at Belfast to be a pernicious practice. —P. B.

LEEKES AND SIZE WORSHIP.

It is not the weight of Leeks and thickness of their stems alone, *plus* purity of blanching, that constitute their value; but the length and uniformity of the blanched parts is an important factor in the case. Great credit was due to Mr. Henry for his weighty achievements recorded on page 169, where "H. W. W." scores a point, and is congratulated. Everybody cannot always be right in everything, and if nobody I have seen has grown Leeks on the Celery-earthing system good enough for me, it is clear that they have been so grown, and perhaps will be again, good enough for some judges at shows.

Short, fat, semi-bulbous Leeks of extraordinary thickness appear to be preferred by certain judges, though not all, to equally pure but thinner stems, uniform throughout, of twice the blanched length and with no suspicion of a bulb. Many old growers do not agree with modern verdicts on the above basis. Let the two types of Leeks be cooked—the short and thick by earthing them above ground, and the relatively thinner stems which have elongated within it, as the result of deep planting in deep and generously enriched soil.

There are not many cooks or Leek consumers with educated palates who would pronounce the much-swollen dumpies "good." The smaller in girth, grown in the good old way, are invariably better when put to the ultimate test. That, however, is not the exhibition test. The eye and not the palate is the dominating power there, and likes to be well filled, hence the bulky Leeks, Onions, Potatoes, Cabbages, and other vegetables which have so often received high honours over products more refined.

If the bigger were, as such, the better, why not carry size worship to its logical issue and choose judges by circumference, with weight? The tall and thin, also the good little men—of whom there are so many—would then give show committees no concern in selecting from them, though these might, perhaps, give just a little trouble in return by judging through the Press, for there are, happily, not a few who, if "in stature small, are in determination great."—A SMALL OLD GROWER.

WEATHER IN LONDON.—Very changeable weather has visited the metropolis during the past seven days. On Thursday and Friday, until the evening of the latter day, when it rained heavily, it was fine, as also was Saturday, the mornings of each day being very frosty. Sunday was a wet day, though there were occasional glimpses of sunshine during the afternoon. In the evening it cleared, the stars shining brightly, and was followed by a sharp white frost on Monday morning, which day was clear and cold. There were very heavy showers on Tuesday, but Wednesday opened clear and cold.

— WEATHER IN THE NORTH.—During the last week of February the weather continued very unsettled—rain, sleet, snow, frosts of from 7° to 11°, and bright sunshine, with occasional high winds, following with short permanence of any. Saturday, with sleety showers, was very disagreeable in the former part; the afternoon improved, but much rain fell during the night. Sunday also brought cold showers, but Monday was brighter, with 2° of frost in the morning. March entered with heavy showers of snow, alternating with gleams of sunshine.—B. D., *S. Perthshire*.

— ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, March 8th, in the Drill Hall, James Street, Victoria Street, Westminster, 1 to 4 P.M. A lecture on "Some of the Plants Exhibited," will be given by the Rev. Professor G. Henslow, M.A., V.M.H., at three o'clock. The Committees will meet as usual.

— ROYAL GARDENERS' ORPHAN FUND.—A meeting of the Committee was held on February 25th, Wm. Marshall, Esq., being re-appointed Chairman for the ensuing year. The guardians for the children elected at the recent meeting were appointed, the mother in most cases undertaking the duties. Authority was given to draw cheques for their payment from date of election. The following special donations were announced—viz., M. Todd, Edinburgh, sale of cut flowers, £30 10s.; H. J. Jones, Esq., Lewisham, boxes at his show of Chrysanthemums, £14 3s. 1d.; J. Gammie, Chiswick, £5 5s.; H. Eekford, Wem, £2; B. Marks, Hardwick, box, 10s.; A. W. G. Weeks, box, 10s.; Jones and Sons, box, 9s. 3d.; J. Hamilton, Byrkley, box, 8s.; J. Pearce, 6s. 6d.; Hook Cottage Gardeners' Society, box, 12s. 6d.

— HALL FOR HORTICULTURE—PROVINCIAL GENEROSITY.—My remarks on page 176 of last week seem to appear at an opportune moment, for we read of the magnanimity in matters horticultural shown by Mr. Henry Yates Thompson of Liverpool in a handsome provision of £6000 for a second Palm house after one of double that cost having been previously granted by the same public spirited benefactor to another Liverpool Park. I should not like to imply that because London is some ten times larger than Liverpool, the proportional equivalent should be justifiably anticipated for London magnificence. The reminder supplied by the said gifts should, however, quicken generosity by others for this metropolis, not, however, without the horticultural societies making earnest in helping themselves, as I indicated last week, so as to deserve support for the creation of the Central Hall for Horticulture.—H. H. R., *Forest Hill*.

— THE WALKER PROMENADE, GATEACRE.—A gift of importance to the residents in this pretty suburban village, which is visited by numbers of the Liverpool inhabitants during the summer, is the handsome promenade in honour of the Diamond Jubilee, which has been constructed at the sole expense of Colonel W. Hall Walker, a son of the late Sir Andrew Barclay Walker, Gateacre Grange. For years the footpath has been narrow and inconvenient, but, thanks to the generous donor, a new promenade of some quarter mile in length has taken its place. This has necessitated the removal of the old boundary wall and hedge, and the erection of a new boundary. This stands back in the field, and consists of a stone wall surmounted by a 4-foot oak palisade. The average width of the footpath is about 24 feet. A fine row of old forest trees has been carefully preserved, and will lend a charm to the appearance during the summer months. Some large Elms have wisely been topped, and altogether the solid stone foundation, covered with limestone chippings, extending from the station past the church, cannot fail to become the highly popular resort that Colonel Walker intended it should be.—R. P. R.

— KEEPING APPLES.—A cool dry cellar is an excellent place to preserve Apples in good condition until the present time. I recently saw some good examples of Blenheim Orange, King of the Pippins, and Striped Beefing which had been stored in a cellar of the above description. A damp ill-ventilated cellar would naturally be detrimental, and a too dry arid atmosphere tends to shrivel fruit.—E. D. S.

— PLANTING HORSERADISH.—The ground on which Horseradish is to be planted ought to be trenched 2 feet deep at least. Manure, if added, should be placed at the bottom. Roots of the thickness of the little finger and about 12 inches long with a crown attached are the best for planting. Discard those with more than one crown. Break off any small roots issuing from the principal root. An open sunny position is the best, but Horseradish will succeed in less favourable situations, but avoid planting under the shade of trees or in competition with their roots.—S.

— CARDIFF HORTICULTURAL SOCIETY.—The ninth annual general meeting of this Society was held in the Town Hall recently, some thirty members being present. Mr. W. C. Peace occupied the chair. The accounts for the past year were duly considered and adopted. The chief matter for discussion was as to the date of the next show, and it was felt that owing to the large number of absentees in August a change was desirable, and it was ultimately decided to hold the show on July 20th and 21st, which is some three weeks earlier than usual. It is to be hoped the change will prove beneficial.

— EARLY POTATOES—SUTTON'S A1.—Our correspondent "H. D.," in his useful article on page 118, February 10th, observed, "It is a pity that Messrs. Sutton & Sons are not able to offer seed (of A1) this season, as it is one of the good things which everyone is trying to get." The writer of the article must have had last season in his mind. This year we are informed there is an ample supply, and there is an excellent illustration of the variety on page 72 in Sutton's "Amateurs' Guide." Our correspondent is usually as wide awake as most gardeners, but he has allowed himself to be caught napping for once.

— CHESTER PAXTON SOCIETY.—At the usual fortnightly meeting, held at the Grosvenor Museum on Saturday, Mr. A. T. Gillanders, High Leigh, delivered a lecture on "Forest Entomology" to the members, who were present in goodly numbers. The lecturer dealt in a comprehensive manner with the life histories of the gall mites, sawflies, beetles, and other insects, often so injurious to forest trees, and gave valuable hints as to the best means of preventing these pests from doing damage. The lecture was copiously illustrated with lantern slides, at the close of which Mr. Gillanders was accorded a hearty vote of thanks.

— PRESENTATION OF THE ALBERT MEDAL TO MR. G. J. SYMONS.—Prior to the departure of H.R.H. the Prince of Wales from Marlborough House, the Council of the Society of Arts attended there, when the Prince, as President of the Society, presented the Albert medal to Mr. George J. Symons, F.R.S., "for the services he has rendered to the United Kingdom by affording to engineers engaged in the water supply and the sewage of towns a trustworthy basis for their work, by establishing and carrying on during nearly forty years systematic observations (now at over 3000 stations) of the rainfall of the British Isles, and by recording, tabulating, and graphically indicating the results of these observations in the annual volumes published by himself."

— A STRANGE THEORY.—There is a good deal that is, to say the least of it, curious in regard to plant life, which never finds its way into the pages of horticultural journals, and a highly popular weekly paper recently advanced a theory about trees feeling the effects of tides. It appears that a Vine grower in Italy is responsible for the idea, and has come to the conclusion after fourteen years' experimenting that the sap of a living tree ebbs and flows in some way in sympathy with the tides of the ocean. According to the account this theorist stated that no tree should be pruned except during the hours of ebb tide. We conclude, of course, that he lives in close proximity to the sea, as no provision, so far as we know, is made for trees and cultivators growing and living 100 miles inland, where little generally is known of the ebbing and flowing of the tide. What is still more remarkable in connection with this theory is that the trees and Vines of this grower and ebb-tide pruner develop splendid foliage, bear heavy crops, and are quite free from the attacks of insects, which spread devastation in the neighbourhood. It seems strange that a course of treatment which insures heavy crops of fruit, and renders trees proof against attacks of insect pests, should be known so little of in gardening circles. That experimenting Italian grower would be a public benefactor if he could prove the truth of his theory to English fruit growers. Perhaps some other reader of the Journal has heard something of this ebb-tide pruning.—H.

— **PRUNUS PISSARDI.**—I have this beautiful Japanese Plum at present in full blossom, a month before its usual time, notwithstanding the recent visitation of frost. I fear it comes much too early in this country to permit of its developing its flowers into fruit, for the hail showers of March are usually very destructive. It is, however, by reason of its beautiful foliage, a highly decorative Eastern tree. It is especially attractive during the late autumnal months.—**DAVID R. WILLIAMSON.**

— **WINCHESTER GARDENERS' ASSOCIATION.**—At the last monthly meeting, on the 22nd ult., through the Hants County Council, Mr. G. Garner of Cadlands Park, Southampton, gave a very instructive and practical lecture on fruit culture under glass. He treated on the Vine, Peach, Nectarine, Strawberry, and Melon, giving hints as to aspect, soil, and general treatment of the several kinds. He was handicapped in not being able to treat the subjects in two or more lectures. A hearty vote of thanks brought one of the most instructive meetings of the winter to a close.

— **EFFECT OF RAIN ON PLANTS.**—**M. Wiesner** has come to the conclusion that the injurious effects alleged to be produced, even by tropical rain, upon leaves and flowers have been greatly exaggerated. He never observed any splitting or tearing of leaves or petals even by the heaviest rain, unless accompanied by a strong wind. When flowers or leaves are bodily torn away by rain it is only when their tissues have already undergone the change which makes them ready to fall. The immunity from the effects of heavy rain is due to the elasticity of the flower or leaf stalk. If these are fixed so as to have no power of movement the impact of a falling body far less than the weight of a heavy drop of rain has a destructive effect on the leaves or petals.—(*"Pharmaceutical Journal."*)

— **POTATOES AND THEIR CULTIVATION.**—**Mr. W. R. Baker**, gardener to Lady Duckworth, Knightleys, contributed an excellent paper on "Potatoes" at the meeting of the Devon and Exeter Gardeners' Association at the Guildhall last week. He referred to the fact that two Devonshire men—Sir Francis Drake and Sir Walter Raleigh—shared the honour of having introduced the Potato into this country. He said a change in Potato seed occasionally was very desirable, as, no matter how good the sort, it was liable to degenerate in time. For thin, light, sandy soil he should use cow manure; and in wet, heavy soil, which was the worst for the Potato, he should use horse manure and good hot lime. In very heavy, wet soil he did not think that lime, guano, and wood ashes could be beaten. About the 20th March was quite early enough for planting, but the seed should be nicely sprouted by storing of each tuber on its base so as to retain the strong central sprout. Four or five shoots on a tuber were too many. He was convinced of the injury resulting from the loss of the premier sprout. The best remedy for scab was chimney soot. A typical collection of the leading kinds of Potatoes now in cultivation were exhibited, and their merits pointed out and commented upon.

— **ANOTHER VALUABLE GIFT TO LIVERPOOL.**—For several years past the Parks and Gardens Committee of the Liverpool City Council has been working manfully to keep pace with the times in the matter of securing open spaces, and although somewhat adversely criticised, the general public must acknowledge the many lasting benefits that are in evidence on all sides, and the bright appearance of the trees and shrubs. There is no doubt that the work of the Committee has left its stamp in the minds of the wealthier of Liverpool's citizens, judging from the fact of the grand playground which was presented to Wavertree by an anonymous donor, and of the magnificent Palm house in Sefton Park, equipped in every way at a cost of £12,000, and presented by H. Yates Thompson, Esq. Now, through the kindness of Mr. Thompson, the residents in the northern part of the city are to be similarly treated by the erection of a house some 120 feet long, at a cost of £6000. This fact was notified at a meeting of the Parks and Gardens Committee held last Wednesday under the presidency of the Chairman, Alderman Joseph Ball, who was supported by the Lord Mayor (Alderman Jno. Houlding), Mr. Yates Thompson, and Mr. Mackenzie, of the firm of Mackenzie & Moncur, the celebrated horticultural builders of Edinburgh. The announcement of the gift was enthusiastically received. Alderman Ball, on behalf of his colleagues, thankfully acknowledged the generous offer of Mr. Yates Thompson, which he was sure the Lord Mayor and Corporation would be delighted to accept on behalf of the citizens. From the plans submitted, the new house will form a great attraction in every way, the design being extremely handsome. It will be situated at the north side of the park, near the bandstand and terrace. As in the case of the Sefton Park building, the contract is entrusted to Messrs. Mackenzie & Moncur of Edinburgh.—**R. P. R.**

— **BEETROOT.**—**Sutton's Blood Red Beet** produces roots of medium size and of a rich dark colour. **Pragnell's Exhibition Beet**, when well grown, is not easily surpassed for handsome form, suitable size, and attractive colour, though not so deep as the preceding variety.—**E.**

— **RIVINA HUMILIS.**—Not long ago I came across a number of these berried plants in good condition. They are rarely, however, met with, in spite of the fact that they are among the most useful of warm greenhouse plants. At almost any time of the year the beauty of the racemes of highly coloured fruit may be enjoyed, and they are extremely useful for various kinds of decoration. The propagation of *Rivina humilis* is simplicity itself, as they are readily raised from seed which germinates freely in heat. Firm potting of the plants is essential to obtain a good set of fruit, and during the flowering period a position close to the glass is advisable to encourage setting. A stove temperature is best while the plants are in bloom, after which they should be removed to a cooler house, otherwise the fruit is apt to fall.—**H.**

— **HEAVY POTATOES.**—At many local flower shows a still popular class is that in which prizes are offered for the heaviest dish of Potatoes. Weight is the only point aimed at, and no matter how ugly and malformed the tubers, those that are heaviest win premier honours. Surely this is not the way to encourage quality among small growers, and quite inconsistent with all good teaching. It may be urged that it is only a novelty; but whether or not, the chance of winning a prize at the show is an inducement to working men, and is an encouragement for them to grow a gross unprofitable variety of Potatoes for the sake of getting first prize in the heavy dish class. As committees are now framing schedules for the ensuing season they will do well to consider this point, and spend the prize money in a direction that will encourage growers to use their endeavours to produce the best and not the heaviest Potatoes. The R.H.S. judging rules give hints on this subject that may be followed with advantage.—**V. T.**

— **SHIRLEY GARDENERS' ASSOCIATION.**—The monthly meeting was held at the Parish Room, Shirley, on the 21st ult., the President, Mr. W. F. G. Spranger, presiding, but owing to the inclement weather there was scarcely an average attendance of the members. Mr. E. T. Mellor, B.Sc. (Lond.), Lecturer in Biology to the Hartley College, Southampton, gave his second lecture on Fungi, entitled "Injurious and Beneficial Fungi." By means of lantern slides the life history of *Peronospora infestans* was given. Wheat rust was also shown to be a great scourge, Australia having lost £2,500,000 in one year by its ravages. The tubercles on all leguminous plants were typical of the beneficial Fungi. A brief discussion ensued on the best methods to lessen the evil caused by the injurious Fungi, the lecturer recommending the burning of the waste of all garden crops, thereby destroying the resting spores. A vote of thanks to the lecturer and to the President closed the meeting.

— **THE DROITWICH EXPERIMENTAL GARDEN.**—The Worcester Union of Workmen's Clubs and Institutes having assistance from the County Council in the town of Droitwich, are to be congratulated on possessing a capital county experimental garden, and the superintendence for it of so excellent an horticulturist as is Mr. James Udale. There lie before me reports of the work done in this garden for the past two years, and it is worthy of note that last year's report is double the dimensions of its predecessor, showing how the work and uses of the garden is growing. It is two acres in extent, but that is ample for all present purposes, and contains some forty-eight varieties of Apples in various forms of training, and Pears, Plums, Cherries, bush fruits, and Strawberries in less variety. During last year nine distinct kinds of vegetables in thirty-five varieties were tested, besides numerous small things, with respect to all of which complete information is furnished. Very complete tables are furnished as to the form of tree, season, and style of pruning, time of opening bloom, gathering of produce, quality of crop and weight. It is interesting to note that the Potato Up-to-Date shows well in the produce table of varieties for the best crop, although for some reason or other the Garton, a variety of great repute in some districts, but not at all so in the south, is valued relatively higher than the preceding, although its relative produce is some 20 per cent. less. Mr. Udale refers in warm terms to the excellence of Homo rape meal manure, spread well over a large bed of Carrots, as having saved them from the wireworm when in danger of being decimated. Naturally the report has most local interest, but it is instructive to find such a garden as this maintained in any county. Would that all counties had a similar one as intelligently managed, it is capable of rendering great service to the county. I notice that during last year no less than 991 persons visited the garden, conclusive evidence of the interest taken in its contents.—**A. D.**

— **ANCIENT FLOWERS.**—Well preserved flowers, which have recently been discovered in Egypt, concealed within tombs of the earlier Pharaohs, have been placed in the Cairo Museum. The commonest of these were white and blue Lotuses, red Poppies, leaves and flowers of Pomegranate, of Saffron, and other species of Crocus. It seems that the flowers of to-day are the same as flourished then, and even the Chrysanthemum had made its appearance in Egypt some 5000 or 6000 years ago.—("Christian World.")

— **THE MARGUERITE FLY.**—If we could banish the Marguerite fly from attacking the plants when in bloom, or at other times, these useful plants would become still more popular. Nursery growers complain of their attacks, and recommend soot in the compost used for potting. Soot water applied to the roots when the pots are full of them is as good a stimulant as anything, and will tend to ward off the flies. Abundance of light and air for the plants while growing assists in building up a stout epidermis through which it is not easy for the flies to pierce.—E.

— **LEAF-MINING PESTS.**—These troublesome pests have always been a nuisance to gardeners. The smeared tin remedies advocated by Mr. Abbey are doubtless good, but would they not be rather unsightly in an ornamental plant house or conservatory? It is at the time the Marguerites are blooming that the small flies deposit their eggs in the leaves. For Celery, however, the plan seems an excellent one, and, to my mind, worthy of adoption. These flies seem the most prevalent in wet seasons, and in damp positions or in the vicinity of trees. I believe, too, that sour leaf soil has something to do with encouraging their increase.—S.

— **PHILLYRÆA DECORA.**—During the last few years this plant has become deservedly popular as an evergreen shrub, and will doubtless continue to advance in favour as its merits become more generally known. Owing to the fact of its having a good natural habit, coupled with fairly rapid growth, it is gradually ousting the Laurel from many places. For positions where a good evergreen shrub is required that will grow quickly, but not wildly, and does not root further than its own radius, this will be found suitable. The habit is sturdy and compact, and it does well in almost any position if given good soil. It roots readily from cuttings of half-ripened wood, inserted in sandy soil in a cold frame during summer. Occasionally it is met with grafted on Privet stocks, but this is objectionable, as it both grows better and lives longer when on its own roots. In trade catalogues it is usually met with under the name of *P. Vilmoriniana*.—D.

— **THE NATIONAL AMATEUR GARDENERS' ASSOCIATION.**—We are glad to see by the report and statement of accounts that this popular organisation is in a sound and satisfactory state. The accounts are admirably clear, and the business of the Association seems to be transacted with great circumspection. It has influential patrons, able officials, and a zealous working committee. Several affiliated societies are registered, and a diversified library is established. Papers are read on well chosen subjects at the different meetings, and amateurs' exhibits arranged, for which merit marks are accorded, the greatest annual aggregate securing medals or winning a place in some of the several challenge trophy contests. The number of members does not appear to be given, but this must be considerable, and the Association seems to be very much alive. A tabulated list of qualified judges selected by the Committee for thirteen different subjects is rather interesting. Out of the total number of twenty-nine two are announced as capable of judging everything—Mr. L. Brown and Mr. J. W. Jones. They certainly ought to have a medal. Messrs. D. B. Crane and B. G. Sinclair only fail in one thing—Cacti and succulents. They should make good this small deficiency. *Per contra*, five judges are presented as equal to only one subject each—great specialists no doubt. Fourteen members are starred in the two columns "Fruit" and "Bush Fruit," but two of those in the second column seem to have been voted out of the first—on the ground, perhaps, that the subjects, as including Apples and Pears, might be too large for them. They must strive for the odd star. Five judges only are up to date in Cacti and succulents, and six in Carnations. Nine are great on Roses, ten each on vegetables and Orchids, eleven on Dahlias and Violas, twelve on Chrysanthemums, thirteen on greenhouse plants, and fourteen on hardy flowers. Then comes a fall to four under the heading "general," and these, as might be expected, composed the distinguished quartette first mentioned. All honour to the four generals of the National Amateur Gardeners' Association. Such elections impart interest and variety to the meetings, which are admirably conducted under the presidency of Mr. T. W. Sanders, and the proceedings accurately recorded by the Honorary Secretary, Mr. Leonard Brown. We wish for the Association increasing prosperity.

— **WEATHER IN NATAL.**—Writing from Maritzburgh, under date February 5th, a correspondent gives us to understand that the weather there in December and January has been warmer than the very mild term that we have experienced. He says: "At Maritzburgh we had ten weeks of excessive drought, and now we have had sixteen days of rain. The temperature five times in five weeks reached 106° in the shade, and several times 95° to 100°."

— **EXPERIMENTS WITH TOMATOES AND POTATOES.**—I notice that your correspondent, "R. P. R.," gives an account of experiments with the above on page 146. In regard to the Tomatoes, growers would no doubt be interested to know the methods by which the plants were grown, and whether on the whole there was any advantage in point of earliness and yield in raising plants in the previous autumn and winter than in raising say in January. The question of earliness in Tomatoes is one of importance to market growers, and experiments that will decide the most economical means by which Tomatoes may be placed in the market at an early date will be of general benefit.—H.

— **STRELITZIA REGINÆ.**—Among the many gorgeous-coloured flowers which have their headquarters in S. Africa, this stands out conspicuously. Although it has been in cultivation in this country for about a century and a quarter, it is not by any means a common plant. Its large, handsome, glaucous foliage would be a sufficient reason for its inclusion in a collection of intermediate house plants, were it not for the beauty of the flowers, which are the chief attraction. The flowers are produced several together on scapes 3 to 4 feet in height, and are brilliantly coloured, the outer portion being orange, the inner dark blue. The curious shape of the flowers, together with the striking contrast of colour, had led to this plant being sometimes called "The Bird of Paradise Flower." Two large plants, carrying seven and nine spikes respectively, are to be seen in flower in the Winter Garden at Kew.—D. K.

— **LIBONIA FLORIBUNDA.**—This old-fashioned winter-flowering plant seems to have lost a good deal of its popularity, as it is not often met with nowadays. It is of easy culture, and compact bushes clothed with bright red and yellow flowers are pleasing in room or conservatory, while the flowers are useful for cutting. *Libonia floribunda*, however, will not endure gas, and placed in rooms lit with it the leaves soon turn yellow and fall off. It is advisable to raise a few fresh plants annually, and the present is a good time to propagate from cuttings. The old plants should be cut back after blooming, and placed in a warm house to encourage fresh growth. During the summer *Libonias* will stand outdoors, and if frequently syringed to keep down spider little difficulty is experienced in obtaining good specimens of this old-fashioned winter-flowering plant.—G.

— **CAMELLIAS.**—The notes by "E. R." on this charming old flower, on page 110, were refreshing, as Camellias during recent years have lost much of their popularity. Fashion in plant life, as in everything else, ebbs and flows, and through its whims one flower comes to the front and another sinks to the background. We remember when the Camellia was the favoured flower for personal decoration, and very much in evidence in the ball-room. Then Dame Fashion said it was stiff, scentless, and artificial looking, and straightway demanded something more light and elegant. The demand was complied with, and the result was that admirers of the Camellia turned their attention to other flowers. So useful and accommodating are the numerous varieties of Camellias, that we cannot, nor would not, dispense with them, and on this account the practical hints of your correspondent will be of service in spite of the fact that it was a trial to his courage to approach the subject.—FASHION.

— **BIRMINGHAM GARDENERS' ASSOCIATION.**—At the usual fortnightly meeting, held on the 21st ult., Mr. W. B. Latham presiding, Mr. B. W. Colebrook read an instructive and comprehensive paper entitled "Express Grape Growing." The essayist's paper teemed with interesting information as to the initial cost of vineries, the treatment of the Vines and their fruit, as well as of the compost. According to Mr. Colebrook's estimate, Grape growing must pay remarkably well. He did not, however, claim a long life for Vines grown on the "express" system, inasmuch as the heavy cropping would in the course of about ten years materially weaken, to the extent that it would pay better to destroy them, and make new borders and plant young Vines. The essay was rendered additionally interesting by accompanying photographs, representative of the fine crops of excellent Grapes grown on the system advocated. An interesting discussion followed, in which references to the prevention and eradication of insect and other pests and maladies formed the chief topic. Mr. Colebrook also gave a list of about a dozen Grapes he could recommend to be grown for general purposes and for sale, such as Black Hamburg, Muscat of Alexandria, Gros Colman, and Black Alicante as the principal varieties.

AN OLD READER'S JOTTINGS.

IN springtime, when hosts of plants are being raised for bedding purposes and vegetation in glass structures is developing rapidly, every inch of space is usually fully occupied, and under such circumstances overcrowding is not easily avoided. The result of growing two plants in a space only large enough to grow one well is painfully apparent where such a practice is followed; but in many instances gardeners are expected to produce so much in a little space that it requires the ingenuity of a "genius" to achieve results satisfactory to all parties.

Sometimes the season favours those who are placed in such difficult positions; they are then able to place many of their bedding plants in rough frames at an early date, and when May comes round they glory in their dwarf vigorous "bedding stuff." The following year perhaps the spring is a severe and changeable one; the plants then have to be kept crowded in the houses till they become "leggy," and the employer wonders why his gardener cannot grow dwarf plants. Some owners of gardens are considerate enough to listen to reason in the matter; but others, unfortunately, demand their "pound of flesh" without explanation. At various times I have met with cases of the latter description, when the gardener's task has been a most unenviable one; but it is satisfactory to find that as the owners of small gardens begin to understand more about gardening they can see for themselves that results must be judged to some extent by the means at command; and when the gardener is also able to put things in a clear way little improvements often result, hence the reason why the rising generation who follow Adam's calling should learn to express their thoughts clearly by the aid of tongue or pen. Thanks to the guiding spirit of "our Journal" we have now "The Young Gardeners' Domain," in which the "thinking workers" of our gardens can the better equip themselves for the stern battle of life. The seed they are sowing now will in due time bring reward.

It is strange how erratic our thoughts sometimes are. I began this note with the intention of keeping to practical work, but now find I have wandered into musings, though perhaps not without supplying some "connecting links" between seasonable work and contemplation. Let me now advance a few practical remarks as to how the temptation to overcrowd plants may be combated. Fortune in regard to weather seems likely to favour us this season, and if the mildness of winter is followed by a genial spring, bedding plants will need placing in cold pits or frames at a comparatively early date. Experienced gardeners are generally extremely cautious about doing this before the end of March or early in April, but by the exercise of a little judgment in regard to the weather, as well as keeping a sharp look out for frosty nights, an immense advantage may be often gained by placing strong plants in frames early in March. Those who have but few glass structures are thus enabled to grow well numbers of bedding plants raised from seed sown in January or February, for, by being able to give them the necessary space, they develop into good plants instead of weak ones, such as overcrowding is bound to produce.

It has often struck me that very few gardens are provided with a sufficient number of cold pits; their utility in springtime needs no pointing out, and throughout the summer and autumn months they can always be turned to good account. It is, perhaps, during the few weeks which precede the beginning of spring that the greatest difficulty is experienced in finding room for plants; but a little ingenuity displayed overcomes many obstacles. A temporary shelf fitted here and there, even at the risk of appearances, helps to forward young seedlings, which later on do well enough on ordinary stages. Pelargoniums which are growing freely at the points should have the centres nipped out; then, although they may be packed somewhat closely together, they do not draw until the young shoots have fairly started, then the time has arrived when more space is absolutely necessary if sturdy plants are to be produced. The stopping just tides over the difficulty during the few most pressing weeks. Simple though this little detail is, it is not the less important, for if we could only accurately ascertain how many bedding plants in Britain annually become spoiled through neglect of timely stopping, the figures would, I think, be startling.

For several years I have followed the practice of placing Pelargoniums in pits and frames much earlier than many gardeners in the same neighbourhood, and I have never had reason to regret doing so. The Ivy-leaved section is the first to be dealt with, and the cool treatment suits them admirably; indeed, when the weather is favourable they seem to thrive better in pits than in houses, and suffer less from the attacks of green fly. The strong plants should be picked out first, and be given as much space as practicable; while the weaker, if arranged by themselves, are not likely to get overwatered, or checked by the growth of stronger plants around them—a point worthy of note in plant culture generally. Zonal Pelargoniums may safely be placed in cold pits shortly after the time when the Ivy-leaved section are found to thrive in similar positions. If possible the opportunity of removing them to pits should be taken

advantage of in bright weather, as damp is usually more likely to injure them than cold, when wet days—accompanied by a low temperature—follow in succession for a considerable time.—AN OLD READER.

NOTES ON ALPINE FLOWERS.

(Continued from page 87.)

CROCUS SIEBERI.

SIEBER'S Crocus is a charming little species, suited either for the border or the rock garden. It is, perhaps, even more appreciated among the alpine flowers than in the border, and its blooms are not so liable to injury and disfigurement as on the level. Its earliness of habit is a great recommendation, and adds much to the favour with which it is viewed by the alpine grower. What is more, it is by no means difficult to grow, as any moderately light soil will enable it to thrive. The early date at which it flowers makes it desirable, however, that it should have a sunny position, so that its little purple flowers may have an opportunity of expanding at their proper season. The colour is described as bright lilac, but the writer prefers to call it light purple, although this is variable. The anthers and filaments are orange, and the stigmata orange-scarlet. According to Mr. George Maw, *Crocus Sieberi* is abundant at high elevations on the mountains of Greece, the Morea, Eubœa, Crete, and the Cyclades. The same authority also says that it flowers in cultivation "about the end of February and early in March," but it often anticipates this, and in the current year flowered about the second week in January. The corms are low in price, although not so cheap as the Dutch varieties of *Crocus*, and ought to be planted as early in autumn as they can be procured.

SANGUINARIA CANADENSIS.

The Blood-root is an exceedingly pretty early flowering plant, which if procured at once will probably flower this year. There are several specific names applied to what may be considered the same plant, but there is also a distinct, large-flowered variety named *grandiflora*, which is more desirable than the typical plant. There is also a variety named *multipetala*, which can be had by those who wish something rarer than the other forms. There is also said to be a double form, but it is doubtful if this is obtainable at any nursery. The Canadian Blood-root delights in a light peaty soil, and some recommend a shady position—a prescription with which the present writer is not disposed to agree, as he finds the flowers more attractive when in a sunny position. They are pure white, and in sun open out quite flat. A large clump of the variety *grandiflora* thus presents an exceedingly pretty appearance when fully open.

The flowers are at first curiously enveloped by the leaves, which unfold themselves when the blooms are past. The leaves are of a pretty glaucous colour. *S. canadensis* is increased by division, and ought not to be left too long out of the ground before replanting. In the rock garden the best place for the Canadian Blood-root is a rather moist spot at the base of the rockery. It is one of the Poppyworts, and has one of the defects of many of the plants included among these generally showy flowers. This is the somewhat fugacious character of the blooms, but it is not so pronounced in the case of the Blood-root as in some others.

ERINUS ALPINUS.

The *Erinus* is a favourite little plant which, unfortunately, some are not able to retain in their gardens and rockeries. It makes a good wall plant when established from seeds, but is only otherwise suitable for the rock garden. Its chief enemies seem heavy winter rains or showers of sleet followed by frost. In a wet winter many plants are thus lost. The Alpine *Erinus* is a native of the Alps of Europe, and in cultivation generally flowers in May and June. The flowers of the type are purplish-crimson, and there are also rose and white varieties which form a pleasing change. It is increased by means of seeds, which are produced freely. In gardens where the old plants die off it is desirable to encourage the production of seeds, so that a succession of plants may be secured by means of self-sown seedlings. A writer on alpine flowers says that it seeds so profusely that if once established on a rockery there is little or no danger of its disappearing. Many persons do not find this correct in their cases, although the present writer has no reason to complain, as not only are there many seedlings produced, but older plants live and flower for years. Old brick rubbish is recommended for mixing with the soil.

HOMOZYNE ALPINA.

This is a little *Tussilago* which some admire on account of its neat habit, the prettiness of its leaves, and the character of the flowers. In some gardens, such as that of the writer, it does not possess the way-faring habits it shows in other soils, and spreads very slowly, so much so, indeed, that it makes hardly any increase. One does not regret this, knowing how freely, or rather rampantly, the fine *Tussilago fragrans* encroaches upon the ground within its reach. As indicated, it is a *Tussilago* in its appearance, and was at one time included by botanists among these plants, whence the name of *Tussilago alpina*, under which it is often seen. It is rather a shy bloomer in my garden, and is most valued for its pretty leaves as a carpet to bulbous plants. It is increased by division, and is readily obtainable from nurseries growing alpine flowers in quantity. Although not one of the choicest of flowers, it has its merits, and one of these is its ability to thrive in partial or almost entire shade.—ALPINUS.

CHEMISTRY IN THE GARDEN.

(Continued from page 604, last vol.)

WE saw in our last article that farmyard manure contained many things valuable to plants as food, but it is very hard to convince some growers that artificial fertilisers may be used to supply crops with the same ingredients. Let us, therefore, examine this part of our subject carefully, and see if the latter can supply plants with the same kind of food as the former.

Farmyard manure is applied to the soil chiefly for the purpose of supplying crops with nitrogen, phosphoric acid, and potash. The nitrogen is present in fresh farmyard manure in an organic condition—that is, combined with other elements to form the organised structure of plants. The food that cattle eat is of a vegetable nature. The solid excreta of the animals is the undigested part of the food, and is of a vegetable or organic character. Plants do not live on organic substances, so the fresh excreta of animals is useless to them. Farmyard manure, however, soon decays. During decomposition the very nature of the manure is changed, and the organic or vegetative character is destroyed, owing to the action of certain living organisms, whose duty it is to convert the organic into inorganic substances.

The food of crops is always absorbed from the soil in an inorganic form. Nitrate of soda is an inorganic substance, and dried blood an organic. The former, therefore, is a plant food, but the latter has to undergo decomposition before it is of any use to crops.

The organic nitrogen in farmyard manure is, during decay, converted into ammonia. The ammonia is then changed by certain nitrifying organisms into nitric acid. The acid when formed in the soil unites with lime and forms nitrate of lime; and it is from this source that plants obtain their chief supply of nitrogen. The nitrate of lime formed by the decomposition of farmyard manure is exactly the same in character and composition as the substance we might buy under that name from the chemist.

When nitrate of soda is applied to soils in which there is a good supply of carbonate of lime the nitric acid of the nitrate of soda unites with the lime and forms nitrate of lime. Some of the nitrate of soda may be absorbed by the roots, but the larger quantity of nitrogen will be taken up as nitrate of lime. If sulphate of ammonia be applied to soil instead of nitrate of soda, the sulphate will be changed by the nitrifying organisms into nitrate of lime. If dried blood be applied instead of either of the former, it will first of all decompose and the nitrogen will be changed into ammonia, and then the ammonia will be converted into nitrate of lime.

The three manures to which we have just referred are all applied for the purpose of supplying plants with nitrogen, and we see that although the three sources are entirely different in character, they all become the same kind of substance—namely, nitrate of lime, before they are taken up by crops. We have put these facts as clearly as possible before our readers with the idea of showing how some of the plant food in farmyard manure must become similar in composition to those chemicals we call artificial manures. We cannot, therefore, understand how your correspondent, "A. D.," can write as he does on page 147 to the effect "that such experiments as he has carried out with artificial manures has led him to realise their practical worthlessness."

Artificial manures never can and never will take the place of good farmyard manure, because the latter has other work to do in the soil besides supplying plants with food; but that a judicious use of the former, in conjunction with the latter, will in most cases produce better crops than either used alone, is a fact beyond dispute, and many are the instances which have come under our notice that might be brought forward to prove the same. Farmyard manure is slow and lasting in its action; artificials act quickly, but are none the less sure.

What would our Grape, Cucumber, Tomato, Chrysanthemum, and other plant growers do without artificial manures? Artificial fertilisers now form the backbone of successful culture, but brains are needed for their proper application.

What we should like to see carried out in practice is (1) Every grower to be his own manure mixer; (2) For each of them to know exactly what his plants require; and (3) To give crops their most appropriate food. We know many artificial manures on the market which are practically worthless; but so long as growers are not able to tell the difference between a good and a bad analysis, these merchants will continue to flourish.

Last year we had a labourer working for us who did not believe in the use of artificial manures, and was not afraid of saying so. When we gave our Tomatoes their first dressing he smiled at what I suppose he considered our foolishness; but long before we gave the plants their last feed, he said: "Well, I never used to believe in them there artificials, but I do now;" and this, to my mind, is a sufficient proof that they are of more value than "A. D." would have us suppose.

—W. DYKE.

(To be continued.)

URCEOCHARIS CLIBRANI.

THIS plant ("R. P. J.") was first shown at the Drill Hall by Messrs. Clibran & Sons, Altrincham, in 1892, and was the result of a cross between *Eucharis grandiflora* and *Urceolina pendula*. The individual flowers, as may be seen in the accompanying woodcut (fig. 30), bear a resemblance to both parents. They are borne in umbels on strong stalks similar to the *Eucharis*, and, unlike the *Urceolina*, are erect on first expanding, drooping slightly when past their best. Being pure white

FIG. 30.—URCEOCHARIS CLIBRANI.

and extremely beautiful in appearance, the flowers prove valuable for decorative purposes. The leaves are broad and as vigorous as those of the *Eucharis*.

APRICOT STOCKS.

ALLOW me to thank "W. S." for his excellent critique on page 121, to which I should have responded sooner, but for the "hope deferred" of some of our fruit tree raisers giving us the benefit of their experience in the matter of stocks for this really choice wall fruit. Of course several manufacturers of fruit trees for sale know little practically of Apricots beyond the saleable article, but there are many exceptions to almost all general rules; not a few of our fruit nurserymen having grown or attempted to grow Apricots against the walls of their buildings, if not on walls specially constructed for the purpose. The late Mr. J. R. Pearson went so far as to endeavour to grow Apricots in glazed sheds, but I am not aware with what success, hence the present representatives of the famous fruit-growing, as well as fruit-tree raising firm, may possibly oblige with a few notes on the subject of both young trees on certain stocks in the nursery, and of their doings when placed in the permanent fruiting quarters.

The late Mr. T. Rivers must have had experience of the hardier varieties of Apricots, for he wrote of the Breda and Alberge as the "only kinds that succeed in England as standards in the open air." He, however, took to growing the Apricot under glass, extolling the fruit so grown, in his first edition of the "Orchard House," as vastly superior in quality to that grown on walls, a mode of culture I also tried and found just as unsatisfactory as that of growing the strong-growing varieties against low walls has always been with me. This, mark, has no reference to the culture of the Apricot under glass as a separate fruit, or in a house by itself, for the failure arose from the mixed system of culture advised and adopted. The trees were certainly healthier, as most of our tenderer fruits are under the restrictive root system, and the drier conditions of the atmosphere, as compared with the "run as you please" outdoor principle of borders for the roots, and the crippling of the limbs on low walls, inducing "canker" or collapse of the branches, and but meagre crops of fruit.

I do not know whether Apricots are still grown under glass at Sawbridgeworth, or to what extent the raising of Apricot trees is practised there, or in such establishments as that of Mr. Bunyard at Maidstone; but the "Orchard House" is in evidence, and to be that in more than name must, according to its founder, contain representatives of all our choicest and tenderest of so-called hardy fruits. This is the very point I wanted to get at—namely, is the "partial or total failure" of Apricots on walls due to influence of unsuitable stocks, or to methods of culture under unfavourable circumstances, and on these points no persons are so able to express an opinion as those thoroughly acquainted with the different varieties of stocks. A few lines from these gentlemen would be very interesting and useful, as there is no question, as "W. S." puts it, of the Apricot being "an uncertain, and fast becoming an unprofitable crop" in this country.

For this there must be some reason, as "W. S." knows trees that "are over sixty years of age as healthy and fruitful as anyone could wish," therefore the success points to something wrong somewhere when Apricots fail, and that mainly through "gumming, and the sudden collapse of the branches." What is it? Lack of natural shelter, defective soil, staple and components, inefficient drainage, or unsuitable stocks! In addition to restriction to low walls, I consider the stock, and the mode of raising a tender fruit in the open ground, as the foundation of all the ills in Apricot culture against walls.

"W. S." further observes, "Of varieties, Hemskerk is the best here; this gives large fruit, good in colour and quality, ripening about the middle of August." Mr. Iggulden said very much the same some time ago in the *Journal of Horticulture*, and the locality of Frome certainly is not one of the best from situation and soil for the Apricot. This variety is a well-known hardy form of Moorpark; and if so, why not more be raised of the same characteristic hardiness, and even better, *plus* the good properties in size, colour, and quality of fruit? The question of stocks also comes very strongly to the fore, standards or riders being mostly worked on the Brussels stock, and the trees of "Kaisha and Moorpark as wall standards are as yet satisfactory." Such records of experience are just what practical cultivators require for guidance, in order to prevent planting trees that may prove unprofitable, and to so choose varieties that there may be a reasonable prospect of remunerative return for investment of capital and reward for labour.

The "dwarf-trained trees of all sorts have been a signal failure," writes "W. S." Nothing possibly could be more decisive—standards a success because on a hardy and suitable stock; dwarf-trained trees a failure perhaps through being on the St. Julien stock. This "saint" proves very delusive, and a fearful sucker on some soils. Peaches and Nectarines gummed dreadfully upon it with me on heavy soils, while the trees were awkward to manage, and to keep them at all healthy on walls frequent lifting had to be resorted to in cold localities.

Mention of this matter raises the question of climate. In the north I have found the hardy Mussel better as a stock for the Apricot than the St. Julien, and the Brussels superior to either, only the trees must have the high wall of the cottage, dwelling, or outbuilding to succeed profitably. The low wall means the narrow border of the garden, and roots restricted correspondingly with the branches. I have nothing to say against the Apricot succeeding even on its own roots or those of seedling Breda stocks. Your able correspondent hits the point exactly when he says "newly planted trees require frequent and careful digging about their roots"—that is, root restriction—"severing any tendency towards grossness, and incorporating with the soil in the course of filling in lime grit, road scrapings—where limestone is used in repairs—and burnt refuse." This is the practice advised by the late Dr. Hogg for keeping the Moorpark Apricot healthy and fruitful from an early stage after planting against garden walls. I have practised it for many years, and found it in every way satisfactory, but instead of patching up old trees on low walls, the better plan is to root them out and plant such varieties as come early into bearing—e.g., Kaisha, and others which are not prone to gumming from the start, as many trees are, mainly because on unsuitable stocks. I thank "W. S." for his very practical article, and trust others will take up the running on similar lines, not only on Apricot, but other branches—indeed, all the ins and outs of practical gardening, for it is just these observations and experiences that carry weight. No evidence tells so forcibly as that which is founded on the experience of real workers. I hope to hear more from them. The simplest matters are often of the greatest value. I did not mean my articles to be "exhaustive," but rather to elicit information for the benefit of those workers with spade and head who are desirous to learn all they can on various subjects in gardening.—G. ABBEY.

DEATH OF MR. RIVERS H. LANGTON.

IT is with deep regret that we have to record the death of this promising rosarian, which occurred on February 19th, at the early age of thirty-six years. The deceased's illness was of brief duration, the death being caused by pneumonia following influenza. Of late years Mr. Langton, whose home was at Raymead, Hendon, had become well-known as an ardent lover and exhibitor of the Rose, which ever held first place in his affection, though he was equally successful in the cultivation and exhibition of the Chrysanthemum. His cheery presence at the exhibitions and meetings he was in the habit of attending will be much missed by his many friends. It will be remembered that, on page 376 of the *Journal of Horticulture*, for October 15th, 1896, Mr. Langton contributed an interesting analysis of the Roses he had shown during that season.

ROSE MURIEL GRAHAME.

IT may be of interest to some of your readers to know that our plant of Catherine Mermet, which sported Muriel Grahame, has again put forth the same variety from another part of the plant. This time it is a sucker-like growth from the base (2 feet lower than before), and bore a really good bloom that was a fac-simile of the Muriel Grahame I have seen from time to time, both upon our own plants from the introducers, as well as on those raised during the past few years from the sport originating here.—A PIPER, *Uckfield*.

GARDEN ROSES.

THOUGH my own supreme favourites among garden Roses are chiefly Chinas, Austrian and Penzance Briars, Teas and Hybrid Teas, I sympathise with Lord Penzance and "D., Deal," in their opinion that such fine Roses as the Gallicas, Hybrid Bourbons, and Hybrid Chinas are not so widely cultivated or frequently exhibited as they ought to be. Most of these are vigorous in constitution, strong growing, highly artistic, and very floriferous. The Dean of Rochester has recorded his conviction that it was an individual bloom of D'Aguesseau, whose colour is crimson richly shaded with purple, that first inspired him with his passionate love of the Rose. One of the sweetest of garden Roses is a Hybrid Noisette, Madame Alfred Carrière, which has, in addition to its soft and graceful beauty, a charming fragrance. It is an admirable Rose for a sheltered south wall.—DAVID R. WILLIAMSON.

ROSES AND CLEMATISES.

WE do not find these two grand flowers grown in connection nearly so often as they deserve. Wherever they have been tried together I have found them form a most popular combination; but perhaps the most pleasing is when grown with our pegged-down Roses, in the way I will endeavour to describe. When pegged-down Roses of the Mdle. Gabrielle Luizet, Mrs. Paul, Margaret Dickson, and similar varieties are grown, we find very few flowers late in the summer. In addition to this, the plants have rather an untidy appearance. Now, if we plant Clematises of the Jackmanni and Viticella type, we get a glorious show of blossom at the very time when the Roses are going past their chief beauty, thus keeping up a succession of flowers in the same bed. There is need, of course, of a little more care and trouble when pruning and pegging down the Roses, but both plants enjoy similar treatment otherwise. The Clematises should be planted near the stools of the strong growing Roses, and alternately with them.

Let us start from the present time, and follow the routine of operations. Our Roses are now being pruned; the wood that flowered so profusely last year when pegged down is cut away entirely. Any Clematis growth around this wood is also cut off. The classes or types named are practically herbaceous perennials, and may therefore be cut down to their base. Having cut away the pegged-down shoots, we strip off any old Clematis growth from the strong upright shoots of the Roses that sprang from the base during late summer and autumn. The ground is cleaned and well mulched around the plants, previously taking the precaution to place some soot around the Clematis stools as a safeguard against slugs, which are particularly fond of the young growths, and eat them off directly they appear.

Now peg down the Rose shoots in the ordinary manner. The Clematis, being close to the Rose stool, and an early grower, will fight its own battle, and push up through any Rose growth, while as the long rods of the latter grow from the base the former will ramble round and among both the upright rod and the Rose growths where pegged down. It is a characteristic of the Jackmanni and Viticella types of Clematis to make long growths and flower from each pair of eyes from July until September, the very time when our Roses of the class named are bare of blossom. The natural effect of Clematises when growing in this form, and allowed to ramble among the Rose growth at will, is one of the most delightful features in any garden.

We can so arrange our beds of pegged down Roses as to get a good contrast of colours from the end of June until the latter part of July, and follow this up with contrasting colours of Clematises from that time until late in the autumn. A few of the Clematises we have found best for this purpose are: Jackmanni section—Jackmanni, dark violet-purple; Jackmanni

alba, white; Alexandria, reddish violet; rubro-violacea, maroon purple; Tunbridgensis, deep bluish mauve; and Gipsy Queen, a very dark velvety purple. Viticella section—Hendersoni, bluish purple; Lady Bovill, greyish blue; Viticella alba, greyish white; and Ascotiensis, deep azure blue.—SUSSEX.

HYBRID PERPETUAL ROSES IN POTS.

ALTHOUGH all pot and other Roses under glass produce a larger number of flowers, and of much better quality when grown steadily, than when hard forced, this class needs such treatment most of all. The Hybrid Perpetuals will not submit to hard forcing so well as the Teas and Noisettes, and a few of the Hybrid Teas. Our own H.P.'s are now well into growth, and showing their flower buds prominently. From this stage they will bear more heat; but if this had been afforded during the early part of January the probability is many of the growths now bearing a healthy flower bud would have been blind. Satisfactory results with these also depend more upon selection of varieties than is the case in other classes. I am alluding more particularly to Roses wanted early, and to assist the display of our lighter coloured Teas, in which case we should select those of few petals, and which open well. There is no better dark red H. Perpetual for the purpose than Général Jacqueminot. Fisher Holmes, Lady Helen Stewart, Bruce Findlay, and Dupuy Jamain are also good. Prince Camille de Rohan gives us a quantity of very dark maroon-shaded blossoms, and opens well.

There are a few Hybrid Teas of exceptional merit for pot work, and as these are freer and more continuous bloomers than the majority of the H.P.'s, they deserve mention here. The best with us is Mrs. W. C. Whitney, a long and very bright bud; Mrs. W. J. Grant, W. F. Bennett, and Souvenir de Wootton are all good reds. The light-coloured varieties, both of H. Perpetuals and H. Teas, can be better replaced by the many excellent Teas and Noisettes. It is the dark reds which we need when forcing the class more particularly under notice.

The plants should be well established in pots, stood in a cool pit or frame by the beginning of November, and be partly plunged and kept close until the buds commence swelling. Then prune rather hard and place them into a temperature of 40° to 45° until the beginning of the year, when they should be showing growth of 2 to 3 inches. From this time onwards the temperature may gradually increase, rising to 55° to 60° by the early part of February, after which a further rise of 5° to 10° will not harm.

The Hybrid Perpetuals seem much more subject to attacks from caterpillars and grubs than the Teas and Noisettes, but I do not find them quite so subject to aphides. So far as culture is concerned they may be treated similarly to Teas after they have made growths of 2 to 3 inches, but it is a decided advantage to grow them more steadily until they reach that stage.—PRACTICE.

GOOD BEDDING ROSES.

WHILE it is not too late for planting a short selection of those varieties most suited for bedding may be of service. I do not mean the ordinary beds or borders of Hybrid Perpetuals and Teas, but Roses to take the place of summer bedding plants generally used in masses on lawns. Not by any means the least suitable for this purpose are such Roses as the Chinas, miniature Polyanthas, and a few of the Bourbons, Teas, and Hybrid Teas. I would rigidly avoid any that are summer bloomers only, and if the following selection be adhered to we shall find a constant show of trusses all through the season.

In bedding Roses it is a great mistake to make use of too many varieties in one bed. One, or at the most two, are ample. A mixture will almost always have a rough appearance, while the effect from other points of view is inferior to that produced when one or two varieties only are relied on. There is also need for judgment in planting, especially as to how far apart they should be. We want an immediate effect, and if planted thickly now it is easy to lift out a few later on should they become unduly crowded. Most of those I will name are dwarf and compact growers. The following Polyanthas may be planted a foot apart each way.

ANNA MARIA DE MONTRAVEL, pure white, of imbricated form, and remarkably free blooming. Parquerette is another pure white, producing its flowers in panicles.

BLANCHE REBATEL.—A deep crimson with rosy shading, and produces immense trusses. A second red Polyantha may be found in Souvenir d'Elise Chatelard.

ETOILE D'OR.—A very free flowering citron and chrome yellow; while Perle d'Or, one of the very best and freest of its class, gives us a deep nankeen yellow with orange centres.

CECILE BRUNNER and GLOIRE DES POLYANTHAS give us a light rose shade with paler centres. The first is exceptionally sweet scented; and the last one of the most prolific of bloomers. Golden Fairy is very changeable; generally a clear buff, with lighter edges, and often pure yellow and pure white blossoms are found upon the same truss.

The above are all perfect little Roses, seldom larger than a shilling, and produced in immense trusses. It is not often they grow more than 15 to 18 inches high, and they are among the hardiest class of Roses we have. Even if cut down to the ground line they seldom fail to push up and make a pretty show the next summer. Nor could we have any Roses better suited for edgings to Rose beds, or as a very dwarf edging to the lawn. I have seen charming effects obtained by several small beds of these Roses, each containing one variety only.

Some of the Chinese or "Monthly" Roses are very useful, and the following may be planted the same distance apart in connection with the Polyanthas named. They are particularly useful because of the rich

colours, such as found in Cramoisie Superieure, rich velvety crimson; Eugène Beauharnais, amaranth; Fabvier, a dazzling semi-double scarlet; Prince Charles, bright cherry red; and Red Pet, dark crimson, with very small flowers. Some authorities class the last named and The Pet (a good white) with the Polyanthas, and they certainly approach that class very closely.

A new Bourbon from Waltham Cross named Lorna Doone must not be missed. This is a deep magenta and carmine, with a suspicion of scarlet. It is a very free bloomer and sweetly scented. I would give this variety 18 inches space each way. Queen of Bedders is another grand Rose from this class. It is a very deep and bright crimson, and one of our best autumnal bloomers.

Among the Teas we find Papa Gontier, a rosy crimson with very long buds; G. Nabonnand, an almost indescribable colour, pale salmon rose shaded with peach and yellow; and Perle des Jardins, a deep yellow of great beauty, and with most handsome foliage. It would be difficult to say too much in favour of these three for bedding, but they are taller than the others named, often reaching 3 feet.

The Hybrid Teas supply La France, Captain Christy, Augustine Guinoisseau, Camoens, Mrs. W. J. Grant, Mrs. W. C. Whitney, Grace Darling, Marjorie, Marquis of Salisbury, and Lady Mary Fitzwilliam, all of which, excepting the last, are about 2 feet high when in full vigour.—OBSERVER.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION BALLOT.

I AM quite willing that "S." (whoever he may be) should (page 173) challenge my remarks on page 132, but I will ask him not to misrepresent my statements. If he will refer again to the page cited he will not find the words he uses "my employer and family," but will find the words "he gave"—i.e., for himself, for his son, and his grandson—thus enlisting their sympathy with the Institution, and bringing them in close touch with it in the earliest days of life, and with a full hope that they would cultivate a taste for that bright ornament "Charity," and further support the Institution in later years. I had not the slightest intention of writing one word *re* the election until I saw the notes of "A. D." (page 101), and while referring to them I felt it was reasonable to call attention to what I thought an oversight on the part of subscribers. "To complain" we have no cause whatever, because it does not affect us in the slightest degree; neither did the candidate ask for support; it was simply suggested to him.

I can assure "S." that whatever has been given by my employer has been given with the purest of motives, and not, as stated, for the purpose of "selecting a candidate at every election," as this is the first candidate he has been interested in. While speaking of liberal subscribers (donors) "S." gives expression to his feelings—"all honour to them for doing so;" but surely such honour should meet with a fair amount of reciprocity, otherwise it amounts to ingratitude on the part of the recipients.

I confess that I should very much like to "find gardeners throughout the country making their presence known," and that in a more substantial form, at the Institution in earlier life. Of the thousands of gardeners in the United Kingdom, what a small percentage subscribe at all! and still more regrettable that a very large percentage of them who do subscribe find their way to the doors after the age of sixty years, at the time when they are at once eligible as pensioners. I note "S." appeals to all gardeners, "whether young or old." I sincerely hope his appeal may prove influential over the minds of many, more particularly with the young, but I fear the power of an initial writer may not carry that weight we would wish to see, as many influential men have met with little response in the way we desire.

If the Institution were entirely in the hands of gardeners, and no donors came forward, it would undoubtedly soon vanish, as the Treasurer informed us at the last meeting. "If donations ceased the Institution would also cease in ten years, as by that time the funds would be completely exhausted," hence the value of donors. I assure "S." I have not the slightest intention to ignore anyone, other than such of those who have the indiscretion to say, "We want help, our coffers are open for your money, you can nominate a candidate, but he must have subscribed two or three pounds or cannot expect to be elected, no matter what his merits may be, and there must be no canvassing, as in other institutions, as that at once disqualifies." To that man or institution I would say, "Please pass on, I do not subscribe to an institution to have my lips sealed;" under such circumstances I prefer to dole out the money where I think it is most needed.

I have read a parable of a pharisee and publican. The former thought himself righteous. To my mind this well applies to the man who has spent the whole of his life and attempted to do nothing until he finds himself within a year or two of the Institution, and then, by great effort, gives two or three years' money to establish his claim. "See how good I've been." The latter (publican) I compare to that man who honestly says "I have spent my life so far and sorry I did not help the Institution when I could, but now it is beyond me, as I really cannot do it." Personally, I would give my vote to the latter, because he does not in the last moments of time try to establish a claim with a mite whereas the former does.

On the other hand there are many gardeners who never have been able to afford to subscribe to the Institution. Sickness, or having frequently to change places through no fault of their own, families, and

many other things have kept them poor, but probably they have used their influence with others, and been the means of obtaining donations from them, directly or indirectly to the charity. I consider such men more worthy of support than the man who says, "I have given £5 and expect the pension of £20 for it to the exclusion of those who have never been able to subscribe," because the "benevolence" of the man who gives £5 in the full hope and expectation of having it returned a thousandfold is pure selfishness. This strictly applies to those over sixty years of age. How long could an institution exist if it were dependant on such subscribers? I do not say this out of any selfish motive, as I have long ago passed that harbour of refuge, "The Gardeners' Royal Benevolent Institution," and sailed into a safer port, and am writing purely in the interests of gardeners and their institution.

I must say "A. D." has so far failed to justify his words "a sham," or to suggest any practical improvement on the present method of election. His "stamp and number in red ink" would give extra work, and the book he speaks of must reveal the names, therefore what benefit would it be? As to his remark on page 146, "to be used in bundles for making certain candidates safe," it is not worthy of comment. I have looked in vain through the last two or three years' lists of subscribers to find out how long your critical correspondent has been a subscriber, and how many annual meetings he could have attended, so as to justify him in calling them sham ones. Will he inform us? I have for some years contributed to and been a supporter of several institutions—one in particular, that gives away more money in one year than the Gardeners' Benevolent is possessed of. The voting is conducted in precisely the same way, with the usual signature as a guarantee of its genuineness, but we enjoy the privileges of exchanging votes—men's for women's, boys' for girls', or aged for juveniles, and *vice-versa*, and never have the slightest complaint; and this has been practised in the Institution perhaps long before "A. D." was born. I consider those who complain of this system do it either because they have had little experience in the management of charities, or for the sake of a form of mental exercise which is not calculated to assist the Institution in any way.—J. OLLERHEAD.

MINT.

SPEARMINT, Peppermint, and Pennyroyal are species of *Mentha*, belonging to the natural order Labiatae. They are hardy perennials, and all natives of Europe, Asia, and Africa, but are chiefly grown in this country, their aromatic leaves being of great service. The Spearmint or garden Mint is well known and appreciated during early spring and summer for its culinary uses. There is in most establishments a regular daily demand for fresh Mint, especially when early Potatoes and green Peas are to be obtained.

Peppermint is cultivated for medicinal purposes. The leaves or young stems may be gathered and tea made of them with boiling water, but the chief use of Peppermint is to form a strong liquid, which is obtained by distillation. The stems are gathered when in flower for this purpose.

Pennyroyal is gathered and dried, then stored away for use in bottles or paper bags. One variety of Pennyroyal named *Mentha pulegium gibraltaricum* was formerly used frequently in carpet bedding, proving very useful for forming edgings of green, compact growth and foliage, dividing lines and groundwork, but a similar plant in growth, and hardier, has taken its place—namely, *Herniaria glabra*.

Spear or garden Mint requires a little systematic cultivation in ordinary moist soil. In dry soils and positions the roots dwindle away. It forms underground rhizomes, which are constantly extending from their original position, so that a bed of Mint requires replanting after a lapse of several years. When the soil is fairly rich and moist Mint will succeed in a position either partially shady or sunny. The present time is a suitable period to break up an exhausted bed. Select young rhizomes found on the outside, and plant them 2 inches deep in rows 8 to 10 inches apart.

After planting, a slight mulch of decayed manure will be beneficial in preventing rapid drying of the soil; but should the weather prove to be very dry in the early part of the summer, applications of water will be necessary. Another method of establishing a bed of Mint is to cut young shoots when about 4 inches long, including a portion of the stem below the soil. Plant at once in rows 8 to 10 inches apart, the cuttings or offsets being inserted about 6 inches asunder. These duly watered and kept fresh will soon become established. April or early in May is a suitable time to carry out this. Keep the bed clear of weeds in summer. In September growth will be completed, when the stems may be cut off close to the soil.

For drying purposes the stems should be cut when the flowers first appear. After the stems have been cleared off in autumn it is a good plan to dress or mulch the bed with a layer of manure, which will not only afford nutriment to the roots, but give a tidy appearance. Mint is easily forced by lifting clumps of roots, placing in a box, and covering with soil, which must be kept moist. A temperature of 50° to 60° will bring it on. The culture of Peppermint is practically the same.

Pennyroyal is a close growing low herb. It is propagated by division, which is best carried out in March or April. Plant the divisions 4 to 6 inches apart in rows 10 inches asunder. In a short time the bed will be a compact mass of growth. The carpet bedding variety should be planted closer, so as to fill up the spaces between as soon as possible. In situations where the plants are subject to damp in winter it is advisable to establish a few vigorous roots in a cold frame, dividing and replanting these in April.—E. D. S.

AFTER FORCING.

How to force, when to force, and what to force are subjects frequently dealt with, and generally this is the end of the matter as far as the scribe is concerned. Once the plant is in flower his end is accomplished, and having detailed the routine of treatment up to this important point, reminders as to the after care are invariably omitted. It must not be so, however, with the gardener who has to produce an annual supply of cut flowers during the early months of the year, and in many cases without being able to give large orders to fill the demand. A gardener so situated, and there are many of them, must think of the future, and so tend his early spring flowering plants that he can rely on them for the next season. It would, perhaps, be wrong to make a charge of waste against the fraternity in this respect, but undoubtedly a want of care exists in many cases, and forced plants, after flowering, are frequently drafted from a heated house to the contrasting conditions of outdoor temperature, and the result is disastrous.

So energetic are our continental neighbours in providing for our horticultural wants that the quantity of Azaleas, Rhododendrons, Deutzias, and other hardwooded flowering plants annually sent to this country for forcing purposes is simply amazing, and the question asked is, What becomes of them all? These plants for the most part are healthy specimens, well furnished with buds and, having bloomed, are in a condition to make healthy growth, which, if properly cared for, means flowers for the future. Do they always get this care? Perhaps so in many instances, but in others they do not, and, having been forced once, they sink into insignificance, and if considered worthy of so much attention they may probably be seen a few seasons afterwards attempting to expand a few solitary blossoms on the outskirts of a shrubbery. It is not always policy to be anxious about peeping behind the scenes, particularly in a garden; but when such is the case, and you see in the out-of-the-way depository for such things groups of recently forced plants with their tender unmaturing growths bowing to the frost or ruthless wind, their pitiable appearance strikes you, and there lies the solution of the query as to what becomes of so many of the imported plants.

There is another side to the question, of course, and a more pleasing one. It is to be found in establishments where plants are forced largely or otherwise, but with a thought to their future utility. Bloom is the main point, and that over growth takes precedence, for it is on this that future usefulness depends. There is no instant banishment to the depository outdoors, there to live or die as the case may be, but a fostering of the plants to produce young shoots, followed by the hardening process, and then a place in the nursery plot or elsewhere until their turn comes round again. Rhododendrons, Azalea mollis, Spiræas, Staphyleas, Lilacs, and a host of others, will amply repay for the care bestowed upon them.

There is no plant more readily forced, or more pleasing in that condition, than the old *Deutzia gracilis*, first when its long branches, covered with snowy unopened buds, strongly resemble the half-developed bells of Lily of the Valley, and then afterwards when the buds open wide and the plant presents a mass of white purity. Many establishments possess stock specimens of *Deutzia*, which season after season are forced, and never fail to produce long flower-covered branches; and on the other hand plants of stunted growth are often seen only producing a tithe of the flowers. The contrast is caused by the difference of treatment after the blooming period, for it is then that care is necessary. The forcing for flowers also forces growth, and that growth must be cared for. From the base of the plants long green branches spring up, and after blooming the old wood should be cut away to make room for the new, applying liquid manure to feed them, and keeping the plants in a warm humid temperature to encourage their extension. After that, removal to a cooler structure in order to harden them, and later on a position outdoors in the summer sunshine to effectually ripen them. There is not much in it after all. It is only the attention that is due to the plants, but if given at the proper time, and with care in potting and watering, the *Deutzias* of this season will bloom as well next and for many years to come until they will become to be as they veritably are in some gardens—old friends. Every gardener who is expected to supply cut flowers early in the year will testify to the usefulness of a number of well-grown *Deutzias* that can be relied on, and it is apparent that the failure, which is by no means uncommon, to obtain an annual supply of bloom from the same plants is due to want of care after forcing.

Spiræa japonica is another plant of the common order, yet we cannot dispense with it for forcing purposes, nor would we do so, as there is nothing to take its place. Any plant of hardy and accommodating nature is sure to be abused, and *Spiræa japonica* is a case in point, as frequently it is either forced to death or after blooming the first time it is bundled outside to make room for something else, without a care for its future welfare. The one extreme is as bad as the other. There are establishments where the forcing order is a regular thing to be given every autumn, and in some such gardens the question of after care is only of minor importance. In other gardens the same plants must do duty again, and the *Spiræas* have to be so arranged that the roots forced this year shall be divided and rested next to come in for active service the season following. A *Spiræa* when in bloom in a pot is a handsome specimen, and as such is admired. Surely, then, it is worth the after care it demands. It is not much, only a few weeks in a warm house, with plenty of water, then a gradual hardening, and finally dividing, if necessary, and planting in the nursery quarter. This, with a little management so that the same clumps are not forced in successive seasons, and *Spiræa japonica* becomes a useful and permanent part of the forcing stock in trade.

Then, again, take Rhododendrons of the roseum and pictum types, also the charming white Cunninghami and others. How useful are dwarf bushes of these for forcing where cut flowers are much in demand! They may be bought easily enough, it is true, well set with buds; but expense is often a grave consideration, and in such cases the gardener must depend on his own resources, though at the same time he is expected to have the flowers. It cannot be done without care, and that care bestowed not only while in bloom, but afterwards when young growth begins. These Rhododendrons are of a hardy, accommodating nature, and suitable varieties may be forced several times over if a season of rest is given between. In some districts the soil is naturally suited for Rhododendrons, and they will thrive in any position in the gardens. In others such is not the case, and it is worth the trouble to prepare a bed for the reception of the plants after forcing by mixing peat and leaf mould with the ordinary soil. Plants, however, must not be discarded directly the flowering is over, but gradually inured to cooler temperature till they may safely be removed outdoors.

Azalea mollis cannot be induced to throw up a wealth of buds in after seasons similar to that with which they are furnished when purchased; still, they will subsequently produce sufficient to merit their being forced again and yet again with proper rest between; but it is only when they receive attention due to them after blooming that this can be expected. The same remarks apply to Lilacs, Staphyleas, and similar members of the forcing section. Plants are often ready to do more for us than we for them, and all these well-known plants, the culture of which is A B C to all gardeners, asks is care, and that care bestowed principally after forcing.—G. H. H.

ARISÆMAS.

THERE are several of these plants known to botanists, though it cannot be said that they are very extensively grown. Indeed it is rare that any are met with except in establishments where a collection of plants of botanical interest is cultivated.

Sir Joseph Hooker says of the genus and of *A. Wrayi* (fig. 31), "The genus *Arisæma* is a remarkable one amongst Aroids for its wide range in latitude from the tropics to far into the north temperate zone; and, as might be expected from this, the elevation it attains is equally remarkable, from the low-lying equatorial regions of the Malayan Archipelago to an elevation of 12,000 feet in the Himalaya. And what is very singular in a genus of so wide a distribution, there are no sectional groups of it more characteristic of the colder than of the hotter regions, or *vice versa*. The nearest ally of *A. Wrayi* is the Javanese and Sumatran *A. filiforme*, Blume. *A. Wrayi* itself is a native of Perak, where it was discovered by Mr. L. Wray, who, in 1884, sent herbarium specimens to Kew from Birch's Hill with the note that the flowers are pale lilac and white, whereas in the cultivated plant they are pale green. In 1888 the same excellent correspondent sent living tubers to Kew which flowered in January, 1889, and from one of these the accompanying figure was made."

It is distinct and rather attractive, and is evidently well adapted to culture in pots. The spathes are neat in shape, and of moderate size; the soft shade of green, the white centre, and the long slender green spadix impart a very graceful appearance to the plant. The leaves are divided into five to nine narrow leaflets, about 8 inches long each, the leafstalks and scape being green and white, dotted with red, giving a very peculiar effect. The plant, like most of its relatives, requires a warm house, a light open soil, abundance of water when in growth and flower, and a period of rest.

CORDON GOOSEBERRIES.

I AM a staunch believer in the method of cultivating Gooseberries as cordons and multiple cordons on walls. The engraving on page 149 shows an extremely fine picture of trees grown in this way. Splendid opportunities are offered in all gardens where newly planted wall trees are put in to fill up the spaces between the permanent trees, even if only for a few years, with Gooseberry cordons. This is a capital plan of utilising wall space, no crop giving more satisfaction than Gooseberries either for early picking for tarts, or for use as dessert when ripe. It is surprising how much earlier the fruit is ready for use from trees growing against walls, especially with an eastern aspect, as compared with bush grown trees in the open. A similar difference, too, is apparent with ripe fruit. When allowed to hang upon the trees till fully ripe the flavour of such sorts as Crown Bob, Whinham's Industry, and Warrington is wonderfully improved.

To obtain the best return in a short time the multiple cordon is better than the orthodox tree of one branch. Those with half a dozen branches do not require more than 15 inches of wall space, especially if they are closely summer pruned, as they should be, admitting light and air freely. Abundance of water at the roots during dry weather is a decided help in promoting a luxuriant growth, encouraging the swelling of the fruit and warding off attacks of red spider, which are partial to Gooseberry leaves. The vigorous upright growing kinds, like the old Champagne, for example, are preferred, as they sooner fill the allotted

space. When the right number of branches has been secured the leading shoots do not require hard pruning, simply removing the point of each to induce a full complement of eyes to push into growth, and thus furnish the branches thoroughly with fruit spurs. Vigorous syringing of the branches in the evening after a hot day is beneficial to the trees, cleanses the fruit from dust, and does much to keep down the spread of insect pests.—E. M.

LONDON'S OPEN SPACES.

III.—HAMPESTEAD HEATH, PARLIAMENT HILL, WATERLOW PARK.

RIGHT away back to the time of the Roman occupation of Britain dates the fame of London's most beautiful breathing ground, Hampstead Heath. It was the old Romans who opened it up. Until they came it was a dense forest that had possibly never been penetrated, but they cut into it in making the great military road called Watling Street, now known as the Great North Road. From their time for a long period onward it was common land, and each man did with its wood or grass what he desired to do, until in 1170 the early chronicler, Fitz-Stephen, spoke of it as that "immense forest, beautiful with woods and groves, full of the lairs and coverts of wild beasts and game, stags, bucks, boars, and wild bulls." To the wonderful sporting rights that must have existed at this time in Hampstead the citizens of London laid claim, and kings confirmed that claim. Henry I. embodied it in one of his most famous statutes, and in charters granted by Henry II., Richard II., and John those rights were confirmed over and over again, and spoken of as inalienable.

The worthy citizens appreciated the good things granted them at Hampstead, where, to again quote Fitz-Stephen, many of them took "great delight in fowling with merlins, hawks, &c., as likewise in hunting." The district was practically disforested in 1218 by Henry III., but much of the great Middlesex wood remained to shelter its wild inhabitants for centuries later. In later years it was known as Hampstead Wood, but all that remains of that wondrous "mass of greenery" are the few copse-like clumps of timber and undergrowth known as "Ken" or "Caen" Woods. That royal glutton and land-thief, Henry VIII., was the first monarch to curtail the citizens' privilege at Hampstead, and he issued a proclamation making it felony for any save at his command to hunt or take game within the lands between "owre Palace of Westminster" to St. Giles-in-the-Fields, and from thence to Isledon (Islington), "our Ladye of the Oke (Gospel Oak), Highgate, Hornsey, and Hampstead." It was while hawking on Hampstead Heath that Henry nearly lost his life, for, following the sport eagerly, he fell headforemost into a muddy ditch, and was nearly suffocated before his attendants could pull him out.

Through the latter part of the seventeenth century Hampstead Heath gained a most unenviable reputation as the resort of robbers and highwaymen, and in the eighteenth century it was notorious. Being a short cut, with several fairly good roads, it was much frequented by merchants and traders, who often rode in strong bodies for protection. Dr. Sibley, a clergyman, was stopped at one of the small cross roads and robbed by a "well mounted rogue, wearing much silver braid and of a convincing manner." This was John Rann, better known as "Sixteen Stringed Jack," who two years after—November 30th, 1774—was hanged at Tyburn. At his trial it was alleged that for a considerable period while

FIG. 31.—ARISÆMA WRAYI.

carrying on his robberies he had been living at Jack Straw's Castle, the well-known inn, as Mr. Grice, a "gentleman of leisure." At this period Hampstead was celebrated as a watering place, and was thronged by the idle, sickly, and dissipated of all classes. There were concerts at the Long Room, raffles at the Wells, entertainments at Belsize, and private marriages at Sion Chapel. The chapel belonged to the publican next door, who advertised a free dinner at his tavern for all folks married at his chapel. The Heath, then much wider and wilder than now, was haunted by gipsies and vagabonds of every description, and on two occasions private stills were discovered in full work, and broken up. Foot-pads abounded, robberies were of daily occurrence; yet, despite these drawbacks, the place was, because of its beauty and surroundings, always a favourite with the public.

It still retains much of its charm, and the 500 acres, over which the County Council now exercises a wise control, is one of the loveliest open spots in England. From it Constable drew much of his inspiration, and he has painted it under all aspects, as his marvellous landscapes in the National Gallery bear witness. Literary men and artists have always loved it. Dickens wrote much of "Little Dorrit" in the room of the tavern, Jack Straw's Castle, that overlooks its wide expanse, and there the chair he used and the table he wrote at are religiously cherished. Not very far away, too, is the Spaniards, that noted old inn from which Mr. Pickwick is supposed to have sent the famous message anent "chops and tomato sauce." For its memories alone Hampstead Heath and its surroundings would be of the deepest interest, but added to these are its numerous natural beauties, making it not merely a metropolitan breathing space of unexampled value, but a national treasure to be preserved as far as possible for all time.

Parliament Hill Fields, now practically made one with Hampstead Heath, were originally a portion of Lord Mansfield's estate known as Caen, or Ken, Wood. The estate and house in 1661 were the property of John Bill, who married Lady Pelham, the daughter of the unfortunate Sir Harry Vane. A portion of the old Gospel Oak Fields is also included in this space, and was formerly the scene of an annual pleasure fair of the most rural character. This fair was abolished in 1864. Gospel Oak is so called from its having been the practice in old times to read aloud under an Oak tree growing on the parish boundary line a portion of the Gospel at the annual boundary beating on Ascension Day. Herrick alluded to this in his "Hesperides."

Dearest, bury me
Under that holy Oak, or Gospel tree,
Where, though thou see'st not, thou may'st
Think upon me,
When thou yearly go'st in procession.

Beneath one of the trees in Gospel Oak Fields, Whitfield, the famous preacher, and the companion of Wesley, used to preach to large audiences of working people. The origin of the name of Parliament Hill is very uncertain. Some antiquaries have traced it back to the holding of shire meetings and similar gatherings upon it. Others assert that it obtained its name because it was the spot chosen by the conspirators of the gunpowder plot as best of all others to witness the destruction of Parliament House by Guy Fawkes.

Another fine open space in the northern part of London is Waterlow Park, which is situated at Highgate. It consists of some 30 acres of finely wooded park land and ornamental waters, and is a most beautiful place. It was formerly known as Lauderdale Park, and the house was for a time the residence of Nell Gwynne, the favourite of Charles II. The house and grounds some twenty years ago became the property of the Waterlow family, and in 1889 Sir Sydney Waterlow munificently presented them to the public as an open space for ever. The old mansion, Lauderdale House, rich with many associations, still stands, and is carefully preserved as a museum and resting place for visitors to the park.—("Lloyd News.")

THE YOUNG GARDENERS' DOMAIN.

PLUMBAGO CAPENSIS.

THE season has now arrived when this beautiful greenhouse plant should be pruned. If the stock is small, it can be easily increased by starting a plant in a temperature of 55° or 60°. In three weeks or a month there will be abundance of cuttings, which root readily under a hand-light or in a propagating frame in light soil. The plants thrive admirably when planted out against the back wall of a greenhouse, if space can be allowed for a border 1½ to 2 feet in width. The compost may consist of three parts loam, one part leaf soil, and one of decayed manure, with a liberal addition of charcoal and sand, and a sprinkling of ¼-inch bones and Clay's fertiliser. If the loam is heavy, a little peat will be of great benefit to the plant.

The shoots should be trained 3 feet apart, and the first season's growth must be cut back to within 3 feet of the ground, then every bud will push forth a shoot, these being annually pruned close back to old shoots or rods. The latter may be allowed 3 feet extension each year until the top of the wall is reached. Three or four good rods will cover a large wall, and when once established may be pruned similar to Vines. No advantage is gained by laying in shoots to form rods at a closer distance than 3 feet. The border should be kept dry when the plant has finished flowering.

The beautiful blue flowers of *Plumbago capensis* are unique in colour, and they will be produced in abundance for three or four months during summer if treated as described. It lasts only a short time when cut for use in vases. Another form, *P. Larpentæ*, is suitable for an edging to borders if in a warm position, and is easily increased by division of the roots in early spring.—J. A.

AN AFTERNOON AT READING.

HAVING recently had the pleasure of visiting Messrs. Sutton and Sons' establishment, I thought it might be interesting to young gardeners like myself if I tried in a few short notes to record my impressions. It would be impossible to attempt to give the number of bulky sacks there are stored in the large rooms which my courteous guide took me through, huge piles of them containing Beans, Peas, and Potatoes for the garden, and more piles of the many seeds for the farm. One could only wonder what becomes of them all.

Passing on, we came to the room where seeds are placed before going abroad; then we found a regiment of women busy hand-picking the broken and bad Peas from the good ones. In another room men were sorting Potatoes, others filling sacks and weighing them ready for going away. In the next room men were filling paper bags of Peas, Beans, and other seeds, for keeping the order room supplied. Passing along we came to the machines in motion, cleaning the various kinds of seeds.

Coming to the vegetable seed order room, shelves, tier above tier, were packed with bags innumerable of the different kinds and varieties of vegetable seeds. The flower seed order room is similar to former, with a bewildering number of drawers for holding the packets of seeds, each drawer having printed on the name the variety contained. It could be seen that everything is done in the most orderly manner—a combination of care with celerity. I must not forget to mention the large railway office, where the labels are directed and affixed to the packages for despatching to their destinations. Then comes the ledger-room with quite an army of clerks at work, while upstairs carpenters were busy making boxes for sending the seeds away.

These nurseries are some little distance away on the confines of the town. The Primulas and Cyclamens afforded a sight not to be forgotten. As we passed through the several houses of Primulas I noted splendidly grown plants of the Star Primula, an excellent variety for decorative purposes, with its many flowering spikes rising high above the foliage; Giant White, with plain and Fern-leaved foliage, and large flowers, 2½ inches across. Equally fine were Rosy Queen, Reading Blue, Reading Scarlet, Gipsy Queen, Double Blue, and Double Pink, the last being a beautiful colour. Not a faulty plant was to be found in the large collection.

The Cyclamens are arranged in a series of long, span-roofed houses, and the plants admirably grown. The handsome marbled foliage and the forest of differently coloured flowers produced a striking effect, among them the white, salmon, crimson, pink, purple, and ruby red varieties being very noteworthy. In other houses Gloxinias were starting into growth, also Begonias, that will, without doubt, make a grand show in their season.

Suitable frames contained healthy dwarf plants of Calceolarias and Cinerarias, that will make a bright show later on. As in the seed department, everything is kept in the most orderly manner, and cleanliness was observable in every house and shed. I think every young gardener might learn a lesson and see a sight not to be forgotten by a visit to the Messrs. Suttons, to whom I am grateful for the privilege and pleasure of having had a look round.—J. B., *Berks.*

FRUIT FORCING.

Cherry House.—To force Cherries successfully ventilation is the main consideration, and requires unremitting attention. A free circulation of air should pass through the house whenever the temperature exceeds 50°, regulating the amount by the conditions of the external atmosphere. Employ fire heat only to maintain 50° through the day, relying on sun heat for advancement, and maintain a night temperature of 40° to 45°. The blossoming over and the fruit swelling, recourse may again be had to gentle syringing. Keep a keen eye on aphides, and promptly fumigate, vapourise, or syringe the trees with an insecticide. Look carefully over the trees for caterpillars—one kind, a species of *Tortrix*, rolls itself up in the leaves, and can be eradicated by squeezing between the finger and thumb, but the other encases itself on the under side of the leaves, giving the appearance of being scalded, and from the leaves passes to the Cherries, eating and spoiling them. The only safe remedy is to search for and destroy the grubs. Supply water or liquid manure to the border as required, keeping trees in pots well supplied, and affording top-dressings of rich material. Pinch side growths at the fourth or fifth leaf, heeling in extensions or growths required to cover vacant spaces.

Cucumbers.—The increased light and sun heat induce greater evaporation, hence necessitate a larger supply of atmospheric moisture; therefore damp the house twice a day, and syringe the plants lightly early on bright afternoons. On cold nights a temperature of 65° is ample, but in mild weather allow 5° more, maintaining 70° to 75° by day, and 80° to 85° or 90° from sun heat, closing early so as to increase the heat to 90°, 95°, or even 100°. Afford liquid manure once or twice a week, always tepid, never too strong. Cut the fruit directly it is large enough. Stop the shoots one joint beyond the fruit; thin the fruits well, removing superfluous
